1 The Set of Integers

1.1 Integers as an Equivalence Relation

Definition 1.1.1: Natural Numbers

The set of natural numbers \mathbb{N} , formulated in ZFC set theory via peano axioms, is the set

$$\mathbb{N} = \{0, 1, 2, \dots\}$$

of natural numbers. Addition and multiplication is also defined.

Definition 1.1.2: Relation on \mathbb{N}^2

Define a relation \sim on \mathbb{N}^2 as follows. We say that $(r, s) \in \mathbb{N}^2$ is related to $(p, q) \in \mathbb{N}^2$ if $r + q = s + p$. We write the relation as $(r, s) \sim (p, q)$.

Lemma 1.1.3

The above relation on \mathbb{N}^2 is an equivalence relation.

Proof. Let $(r, s) \in \mathbb{N}^2$. Since addition in \mathbb{N} is commutative, we have $r + s = s + r$ so that $(r, s) \sim (s, r)$. Thus \sim is reflexive.

Suppose that $(r, s) \sim (p, q)$. Then $r + q = s + p$. Rewriting the expression as $p + s = q + r$ by commutativity of addition, we conclude that $(p, q) \sim (r, s)$. The same argument shows that $(p, q) \sim (r, s)$ implies $(r, s) \sim (p, q)$. Thus \sim is symmetric.

Suppose that $(r, s) \sim (p, q)$ and $(p, q) \sim (v, w)$. Then we have that $r + q = s + p$ and $p + w = q + v$. We can deduce that

$$\begin{aligned} r + q &= s + p \\ r + q + v &= s + p + v \\ r + p + w &= s + p + v \\ r + w &= s + v \end{aligned}$$

Hence $(r, s) \sim (v, w)$ and \sim is transitive. We conclude that \sim is an equivalence relation. \square

Definition 1.1.4: Integers

Define the set of integers \mathbb{Z} to be the set of equivalence classes of $\mathbb{N} \times \mathbb{N}$ under \sim .

1.2 Divisibility

Definition 1.2.1: Divisibility

Let $a, b \in \mathbb{Z}$. We define the relation

$$a|b$$

if and only if there exists some $k \in \mathbb{Z}$ such that $b = ak$. We say that a divides b in this case.

Proposition 1.2.2

Let $d, m, n \in \mathbb{Z}$. The relation $|$ has the following properties and thus is a partial order in \mathbb{N} .

- Reflexive: $n|n$
- Anti-symmetric: $m|n$ and $n|m \implies m = n$
- Transitive: $d|n$ and $n|m \implies d|m$
- Linear: $d|n$ and $d|m \implies d|(an + bm)$ for any $a, b \in \mathbb{Z}$
- $1|n$
- $n|0$

Proof. We prove antisymmetry and transitivity and leave the others for the reader. Let $m, n, d \in \mathbb{Z}$.

- (Antisymmetry) If $m|n$ and $n|m$ then there exists some $k_1, k_2 \in \mathbb{N}$ such that $n = k_1m$ and $m = k_2n$ thus $n = k_1k_2n$. Then $k_1k_2 = 1 \implies k_1 = k_2 = 1$ and $m = n$
- (Linearity) If $d|n$ and $n|m$ then there exists $k_1k_2 \in \mathbb{N}$ such that $n = k_1d$ and $m = k_2n$. Then $m = k_2k_1d$ thus $d|m$

□

These properties will come up again and again and will be the foundation of number theory. It is safe to say that number theory is built upon the notion of divisibility.

1.3 The Division Algorithm

This section is dedicated to develop the Euclidean algorithm, a means to find the greatest common divisor. The gcd is a central notion in number theory as well.

Definition 1.3.1: Greatest Common Divisor

Suppose that $m, n \in \mathbb{Z}$. A number $d \in \mathbb{N}$ such that

- $d \geq 0$
- $d|m$ and $d|n$
- $e|a$ and $e|b \implies e|d$

is called the greatest common divisor of m and n , denoted $\gcd(m, n)$.

In contrast to the greatest common divisor, we also have the lowest common multiple. Although they work as a pair, we often see the notion of gcd come up more than lcm.

Definition 1.3.2: Lowest Common Multiple

Suppose that $m, n \in \mathbb{Z}$. A number $l \in \mathbb{N}$ such that

- $l \geq 0$
- $m|l$ and $n|l$
- $m|e$ and $n|e \implies l|e$

is called the lowest common multiple of m and n , denoted $\text{lcm}(m, n)$.

Beware that both of these definitions does not imply the uniqueness of such a number. However, with a little work, we will see that both of them are indeed unique. Readers should think about whether the existence of these numbers is guaranteed as well.

Proposition 1.3.3

Let $m, n \in \mathbb{Z}$. Then the numbers $\gcd(m, n)$ and $\text{lcm}(m, n)$ are unique.

Proof. By the third property of both numbers, we must have if c, d are $\gcd(m, n)/\text{lcm}(m, n)$, then $c|d$ and $d|c$ thus $c = d$ and $\gcd(m, n)/\text{lcm}(m, n)$ is unique. □

We will see more on gcd and lcm when we deal with factorization. For now, we turn our heads to the

division algorithm. This algorithm proves to us that upon dividing two integers, as long as they are not divisible by one or the other, you can always guarantee a remainder smaller than the dividend.

Theorem 1.3.4: The Division Algorithm

Let $a \in \mathbb{N}$ and $b \in \mathbb{Z}$ with $b \neq 0$. Then there exists unique $q, r \in \mathbb{Z}$ such that

$$b = aq + r$$

with $0 \leq r < a$.

Proof. We prove existence first by considering three cases.

Cases 1: b is divisible by a . If b is divisible by a then there exists $k \in \mathbb{Z}$ such that $b = ka$ thus $k = q$ and $r = 0$.

Case 2: b is positive and a does not divide b . Let

$$S = \{b - ka \in \mathbb{N} \mid k \in \mathbb{N}\}$$

Then $S \subseteq \mathbb{N}$ thus we can apply the well-ordering principle to S . Let r be the least natural number in S . Then $r \in S$ implies $r = b - ka$ for some $k \in \mathbb{N}$. Thus $b = ka + r$ for some k and r . We show that $r < a$. Suppose for a contradiction that $r \geq a$. Then $u = r - a \in \mathbb{N}$ and

$$b = ka + r \implies b = ka + (u - a) \implies b = (k - 1)a + u$$

thus $u \in S$ and $u < r$, contradicting the fact that r is the least element in S . Thus $r \leq a$. If $r = a$, then

$$b = ka + a \implies b = (k + 1)a$$

which means that $a \mid b$ which is false in our case. Thus we must have $r < a$.

Case 3: b is negative and a does not divide b . Then apply the exact same argument to the number $-b$ to get $(-b) = ka + r$ and $b = -ka - r$. Let $k' = -k - 1$ and $r' = -r + a$. Then

$$b = -ka - r = k'a + a + r' - a = k'a + r'$$

Since we have $0 \leq r < a$, we have $-a < -r \leq 0$ and $0 < r' \leq a$. Again $r' \neq a$ or else $a \mid b$ which contradicts our assumption.

We now prove uniqueness. Suppose that $b = aq_1 + r_1$ and $b = aq_2 + r_2$. Then $r_1 - r_2 = a(q_2 - q_1)$. We know that $-a < r_1 - r_2 < a$ thus $-a < a(q_2 - q_1) < a$ and $-1 < q_2 - q_1 < 1$ which is impossible for integers q_1, q_2 unless $q_1 = q_2$. If $q_1 = q_2$ then $r_1 = r_2$ and we are done. \square

The division algorithm does not require b to be larger than a . In fact, if a is larger than b , then the division algorithm simply gives a itself as the remainder. Before we reach our conclusion, we need one more proposition.

Proposition 1.3.5

Suppose that $m \geq n > 0$ are natural numbers with $m = qn + r$ for some $q, r \in \mathbb{N}$. Then

$$\gcd(m, n) = \gcd(n, r)$$

Proof. Suppose that $d = \gcd(m, n)$. Then we know that $d < n$ from definition. We want to show that d satisfies the three results of a gcd but in terms of n and r . Since $d \mid n$ and $d \mid m$, by linearity we must have $d \mid r$.

Now suppose for a contradiction that there exists e such that e is a common divisor of n and r and $e > d$. Then $e|n$ and $e|r$ by definition thus $e|m$ by linearity. $e|m$ and $e|n$ implies that e is a larger common divisor of m and n than d . However this is not possible since d is assumed to be the largest among the common divisors. This is a contradiction thus $d = \gcd(n, r)$ and we are done. \square

Theorem 1.3.6: Euclid's Algorithm

Suppose that $m \geq n > 0$ are natural numbers. We have the following inequalities.

$$m = nq_1 + r_1 \text{ with } 0 < r_1 < n$$

$$n = r_1q_2 + r_2 \text{ with } 0 < r_2 < n$$

$$r_1 = r_2q_3 + r_3 \text{ with } 0 < r_3 < n$$

$$\dots\dots\dots$$

$$r_{k-2} = r_{k-1}q_k + r_k \text{ with } 0 < r_k < r_{k-1}$$

$$r_{k-1} = r_kq_{k-1}$$

From this, we have $r_k|r_{k-1}$, $r_k|r_{k-2} \dots r_k|n$ and $r_k|m$.

Proof. The first part of the results is due to the repeated use of the division algorithm. For the second part, we have

$$\gcd(m, n) = \gcd(n, r_1) = \gcd(r_1, r_2) = \dots = \gcd(r_{k-1}, r_k) = r_k$$

and we are done. \square

Lemma 1.3.7: Bezout's Lemma

Let $a, b \in \mathbb{Z}$ such that they are not both 0. Then there exists $x, y \in \mathbb{Z}$ such that

$$ax + by = \gcd(a, b)$$

Proof. Reconstruct x and y using the Euclidean Algorithm. This is possible since $\gcd(m, n) = r_k$ and every r_1, \dots, r_{k-1} has a factor of r_k in it. \square

Lemma 1.3.8

Let $a, b \in \mathbb{Z}$ such that they are not both 0. Then the equation

$$ax + by = \gcd(a, b)$$

has an infinite number of integer solutions.

Proof. Using Bezout's Lemma, we conclude that (x_0, y_0) is a solution to the equation. But then

$$(x_0 - bt, y_0 + at)$$

are also solutions for $t \in \mathbb{Z}$ since

$$a(x_0 - bt) + b(y_0 + at) = ax + by = \gcd(a, b)$$

\square

Corollary 1.3.9

Let $a, b \in \mathbb{Z}$ such that they are not both 0 and $d \in \mathbb{Z}$. Then d divides a and b if and only if $d \mid \gcd(a, b)$.

1.4 Unique Factorization**Definition 1.4.1: Prime Numbers**

We say that $n \in \mathbb{N}$ is a prime number if and only if it has exactly two factors, which is 1 and n . Else n is composite.

Lemma 1.4.2

Every integer is divisible by a prime.

Lemma 1.4.3

Every integer $n > 1$ can be written as a product of primes.

Theorem 1.4.4

There is an infinite number of primes.

Proposition 1.4.5: Euclid's Lemma

Suppose that $p, m, n \in \mathbb{N}$, with p prime and $m, n > 1$. Suppose that $p \mid mn$. Then p divides at least one of m or n .

Proposition 1.4.6

Suppose that p is a prime such that $p \mid a_1 a_2 \cdots a_k$. Then $p \mid a_i$ for some $i \in \{1, 2, \dots, k\}$

Theorem 1.4.7: Fundamental Theorem of Arithmetic

Suppose that $n \neq 0$ is a natural number. Then there exists exactly one prime factorization for every n , meaning that the decomposition

$$n = \prod_{k=1}^n p_k^{s_k}$$

where p_k is prime exists and is unique.

Theorem 1.4.8

Suppose that $m, n \in \mathbb{N}$. Suppose that

$$m = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}$$

$$n = p_1^{\beta_1} p_2^{\beta_2} \cdots p_q^{\beta_q}$$

with $p_1 = 2, p_2 = 3, p_3 = 5 \dots$. Without loss of generality $r \leq q$. Then

$$\gcd(m, n) = p_1^{\min(\alpha_1, \beta_1)} p_2^{\min(\alpha_2, \beta_2)} \cdots p_q^{\min(\alpha_q, \beta_q)}$$

$$\text{lcm}(m, n) = p_1^{\max(\alpha_1, \beta_1)} p_2^{\max(\alpha_2, \beta_2)} \cdots p_q^{\max(\alpha_q, \beta_q)}$$

Proposition 1.4.9

Suppose that m and n are natural numbers. Then

$$\gcd(m, n) \times \text{lcm}(m, n) = m \times n$$

Proof. Since $\min\{a, b\} \cdot \max\{a, b\} = ab$, from the above theorem, we have that $\gcd(m, n) \times \text{lcm}(m, n) = m \times n$ and we are done. □

2 Rational Numbers

2.1 Introduction to Rationals

Definition 2.1.1

Define a relation \sim on \mathbb{Z}^2 as follows. We say that $(a, b) \in \mathbb{Z}^2$ is related to $(c, d) \in \mathbb{Z}^2$ if $ad = bc$. We write the relation as $(a, b) \sim (c, d)$.

Lemma 2.1.2

The above relation \sim on \mathbb{Z}^2 is an equivalence relation.

Definition 2.1.3: Rational Numbers

Define the set of rational numbers \mathbb{Q} to be the set of equivalence classes of $\mathbb{Z} \times \mathbb{Z}$ under R . Each equivalence class $E_{(a,b)}$ is denoted by $\frac{a}{b}$.

Definition 2.1.4: Reduced Form

Suppose that $a \in \mathbb{Q}$. $a = \frac{r}{s}$ is a reduced form if

- $s > 0$
- $\gcd(r, s) = 1$

Theorem 2.1.5

For every $x \in \mathbb{Q}$, x has exactly one reduced form.

3 Real Numbers

3.1 Real Numbers as Dedekind Cuts

Definition 3.1.1: Dedekind Cuts

A dedekind cut A is a subset of \mathbb{Q} such that the following are true.

- A is non-empty
- $A \neq \mathbb{Q}$
- For all $x, y \in \mathbb{Q}$ such that $x < y$ and $y \in A$, we have that $x \in A$
- For all $x \in A$, there exists $y \in A$ such that $x < y$

Definition 3.1.2: Real Numbers

We define the set of real numbers \mathbb{R} as the set of all dedekind cuts of \mathbb{Q} .

Proposition 3.1.3

Define addition, subtraction, multiplication, division as follows. Then the resulting set is also a dedekind cut.

- $A + B = \{a + b : a \in A \text{ and } b \in B\}$
- $A - B = \{a - b : a \in A \text{ and } b \in \mathbb{Q} \setminus B\}$
- $A \times B = \{a \times b : a \in A \text{ and } b \in B\}$ if $A, B \geq 0$ or $A, B \leq 0$. If at one of $A, B < 0$ then use the identity $-(-A \times B)$ or $-(A \times -B)$ depending on whether $A < 0$ or $B < 0$ respectively.
- $A/B = \{a/b : a \in A \text{ and } b \in \mathbb{Q} \setminus B\}$ if $A, B \geq 0$ or $A, B \leq 0$. Use the similar approach as multiplication when one of $A, B < 0$.

Proposition 3.1.4

The following are true regarding addition of real numbers.

- Associative: For all $x, y, z \in \mathbb{R}$, $(x + y) + z = x + (y + z)$
- Additive Identity: $0 \in \mathbb{R}$ is a real number that satisfies $x + 0 = x = 0 + x$ for all $x \in \mathbb{R}$.
- Additive Inverse: For all $x \in \mathbb{R}$, $-x \in \mathbb{R}$ is a real number that satisfies $x + (-x) = 0 = (-x) + x$
- Commutative: For all $x, y \in \mathbb{R}$, $x + y = y + x$

Proposition 3.1.5

The following are true regarding multiplication of real numbers.

- Associative: For all $x, y, z \in \mathbb{R}$, $(x \cdot y) \cdot z = x \cdot (y \cdot z)$
- Multiplicative Identity: $1 \in \mathbb{R}$ is a real number that satisfies $x \cdot 1 = x = 1 \cdot x$ for all $x \in \mathbb{R} \setminus \{0\}$.
- Multiplicative Inverse: For all $x \in \mathbb{R} \setminus \{0\}$, x^{-1} is a real number that satisfies $x \cdot x^{-1} = 1 = x^{-1} \cdot x$.
- Commutative: For all $x, y \in \mathbb{R}$, $xy = yx$.

3.2 Irrational Numbers

Proposition 3.2.1

The function $\iota : \mathbb{Q} \rightarrow \mathbb{R}$ given by

$$\iota(p) = \{q \in \mathbb{Q} \mid q < p\}$$

defines a bijection from \mathbb{Q} to $\iota(\mathbb{Q})$.

This shows that we can identify \mathbb{Q} as a subset of \mathbb{R} .

Definition 3.2.2: Irrational Numbers

Let $x \in \mathbb{R}$. We say that x is an irrational number if $x \notin \text{im}(\iota)$.

Theorem 3.2.3

There exists an irrational number.

Proof. We want to show that there is an irrational number represented by a dedekind cut such that its square is 2. Consider the set $A = \{x \in \mathbb{Q} : x < 0 \text{ or } x^2 < 2\}$. A is non-empty since $0 \in A$. $A \neq \mathbb{Q}$ since $3 \notin A$. Suppose $p \in A$. We then need to show that $q \in A$ whenever $q < p$. When $0 \leq q < p$, we have $0 \leq q^2 < p^2$ from ordering of rationals. When $q < 0$, then $q \in A$ by definition of A . Thus this is true. Now we need to show that there is always a rational q larger than p which is in A . Choose $q = \frac{2p+2}{p+2}$, then $p < q$ and $q^2 < 2$. Thus A is a dedekind cut.

Now consider $A \times A$. We have $A \times A \leq 2$ since for all $x, y \in A$, we have $x^2 < 2$ and $y^2 < 2$ and thus $xy < 2$ whenever $xy \geq 0$. Thus the set $A \times A = \{r \in \mathbb{Q} : r < 0 \text{ or } r = xy \text{ for some } x, y \in A \text{ and } x, y > 0\}$ is less than or equal to 2. We know that $A \times A$ is a dedekind cut. But we want to know if $A \times A$ represents the number 2. Suppose that $u \in A \times A$. Then we know that from A , there exists a number $v \in A$ such that $u < v^2 < 2$. And this applies for every u . Then we know that $A \times A = 2$ since $A \times A = \{x \in \mathbb{Q} : x < 2\}$, which is our definition of rational numbers with dedekind cut.

We have proved that there exists a dedekind cut such that its square is 2. But is that dedekind cut irrational? We now represent A with $\sqrt{2}$. Suppose that $\sqrt{2}$ is rational. Then we can write it as $\frac{m}{n}$ in reduced form. Then we have $2n^2 = m^2$. Then $2|m^2$ thus $2|m$. Let $m = 2k$ for some $k \in \mathbb{N}$. Then $2k^2 = n^2$ which similarly implies that $2|n$. This contradicts the fact that $\frac{m}{n}$ is in reduced form, thus $\sqrt{2}$ is in fact not rational, and is an irrational number. \square

3.3 Ordering and Absolute Values

Definition 3.3.1: Order

If A, B are dedekind cuts then we say that $A < B$ if and only if $A \subset B$.

Theorem 3.3.2: Bernoulli's Inequality

For all $x \geq -1$ and $n \in \mathbb{N}$,

$$(1+x)^n \geq 1+nx$$

Proof. We prove the inequality by induction on n . In the case of $n = 1$, we have $1+x \geq 1+x$, which is true for all x . Now suppose that the inequality works for some $n \in \mathbb{N}$. We have

$$\begin{aligned} (1+x)^{n+1} &\geq (1+x)(1+nx) && \text{(Induction Hypothesis and } x \geq -1) \\ &= 1 + (n+1)x + nx^2 \\ &\geq 1 + (n+1)x && \text{(since } x^2 \geq 0) \end{aligned}$$

Thus we have the Bernoulli's Inequality by the principle of mathematical induction. \square

The absolute value is an important function when it comes to defining useful concepts such as distances in the field of real.

Definition 3.3.3: The Absolute Value

The absolute value of a real number x is defined by

$$|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x \leq 0 \end{cases}$$

The absolute value has some properties that are extremely useful in certain circumstances, notably number 4 and 5.

Proposition 3.3.4

The absolute Value has the following properties

1. $|x| \geq 0$
2. $|xy| = |x||y|$
3. $|\frac{x}{y}| = \frac{|x|}{|y|}$
4. $|x + y| \leq |x| + |y|$
5. $||x| - |y|| \leq |x - y|$

Proof. I left out the proofs of (2) and (3) since they are simply obtained via case by case analysis.

1. When $x \geq 0$ we have $|x| = x \geq 0$. When $x < 0$ we have $|x| = -x > 0$
2. We start by squaring the left hand side of the inequality.

$$\begin{aligned} |x + y|^2 &= (x + y)^2 \\ &= x^2 + 2xy + y^2 \\ &\leq |x|^2 + 2|x||y| + |y|^2 \\ &= (|x| + |y|)^2 \end{aligned}$$

Since the both sides of the inequality is non-negative, we can take the square root on both sides, thus obtaining $|x + y| \leq |x| + |y|$.

3. Choose x to be $x - y$ in (4) and we obtain $|x| - |y| \leq |x - y|$. Similarly, choosing y to be $y - x$ in (4), we find that $|y| - |x| \leq |y - x| = |x - y|$. Thus we have $||x| - |y|| \leq |x - y|$.

□

3.4 The Binomial Theorem**Definition 3.4.1: The Binomial Coefficient**

Let $n, r \in \mathbb{N}$ with $n > 0$. We define the binomial coefficient $\binom{n}{r}$ to mean the number $\frac{n!}{r!(n-r)!}$ when $r \leq n$. When $r > n$ then $\binom{n}{r} = 0$.

Proposition 3.4.2

Let $n, r \in \mathbb{N}$ with $0 < r < n$, we have $\binom{n}{r} = \binom{n}{n-r}$.

Proposition 3.4.3

Let $n, r \in \mathbb{N}$ with $0 < r < n$, we have $\binom{n}{r-1} + \binom{n}{r} = \binom{n+1}{r}$.

Theorem 3.4.4: The Binomial Theorem

Suppose $a, b \in \mathbb{R}$. Then

$$(a + b)^n = \sum_{k=0}^n \binom{n}{k} a^{n-k} b^k$$

Theorem 3.4.5

[Vandermonde's Theorem] Suppose that $a, b, n \in \mathbb{N}$. Then

$$\binom{a+b}{n} = \sum_{k=0}^n \binom{a}{k} \binom{b}{n-k}$$

4 Complex Numbers

4.1 Introduction to Complex Numbers

Definition 4.1.1: Complex Numbers

Define the set of complex numbers \mathbb{C} to be \mathbb{R}^2 . For each pair of real numbers $(a, b) \in \mathbb{R}^2$.

For each pair of real numbers $(a, b) \in \mathbb{R}^2$, we write $a + b\sqrt{-1}$ to represent the pair (a, b) to indicate that we are working over the complex numbers.

Definition 4.1.2: Complex Addition

Define complex addition to be the function $+: \mathbb{C} \times \mathbb{C} \rightarrow \mathbb{C}$ given by

$$(a, b) + (c, d) = (a + c, b + d)$$

Definition 4.1.3: Complex Multiplication

Define complex multiplication to be the function $\cdot: \mathbb{C} \times \mathbb{C} \rightarrow \mathbb{C}$ given by

$$(a, b) \cdot (c, d) = (ac - bd, ad + bc)$$

Proposition 4.1.4

The following are true regarding addition of complex numbers.

- Associative: For all $x, y, z \in \mathbb{C}$, $(x + y) + z = x + (y + z)$
- Additive Identity: $0 = (0, 0) \in \mathbb{C}$ is a complex number that satisfies $x + 0 = x = 0 + x$ for all $x \in \mathbb{C}$.
- Additive Inverse: For all $x \in \mathbb{C}$, $-x \in \mathbb{C}$ is a complex number that satisfies $x + (-x) = 0 = (-x) + x$
- Commutative: For all $x, y \in \mathbb{C}$, $x + y = y + x$

Proposition 4.1.5

The following are true regarding multiplication of complex numbers.

- Associative: For all $x, y, z \in \mathbb{C}$, $(x \cdot y) \cdot z = x \cdot (y \cdot z)$
- Multiplicative Identity: $1 = (1, 0) \in \mathbb{C}$ is a complex number that satisfies $x \cdot 1 = x = 1 \cdot x$ for all $x \in \mathbb{C} \setminus \{0\}$.
- Multiplicative Inverse: For all $x \in \mathbb{C} \setminus \{0\}$, x^{-1} is a complex number that satisfies $x \cdot x^{-1} = 1 = x^{-1} \cdot x$.
- Commutative: For all $x, y \in \mathbb{C}$, $xy = yx$.

Definition 4.1.6: Conjugation

Define conjugation to be a function $\bar{\cdot}: \mathbb{C} \rightarrow \mathbb{C}$ given by

$$\overline{(a, b)} = (a, -b)$$

We say that $(a, -b)$ is the conjugation of the complex number $(a, b) \in \mathbb{C}$.

Proposition 4.1.7

The following are true regarding conjugation.

- For all $z \in \mathbb{C}$, $\bar{\bar{z}} = z$
- For all $z, w \in \mathbb{C}$, $\overline{z + w} = \bar{z} + \bar{w}$

- For all $z, w \in \mathbb{C}$, $\overline{zw} = \overline{z}\overline{w}$

4.2 Polar Representation of Complex Numbers

Definition 4.2.1: Modulus

Define modulus to be the function $|\cdot| : \mathbb{C} \rightarrow \mathbb{R}$ given by

$$|(a, b)| = \sqrt{a^2 + b^2}$$

We say that $|(a, b)|$ is the modulus of the complex number $(a, b) \in \mathbb{C}$.

Proposition 4.2.2

Then the following are true regarding the modulus.

- $|z|^2 = |z||\bar{z}|$
- $|\bar{z}| = |z|$
- $|zw| = |z||w|$
- $z\bar{z} = |z|^2$
- $|z + w| \leq |z| + |w|$
- $|z - w| = ||z| - |w||$

Definition 4.2.3: Argument

Define argument to be the function $\arg : \mathbb{C} \rightarrow \mathcal{P}(\mathbb{R})$ given by

$$\arg((a, b)) = \left\{ \theta \in \mathbb{R} \mid \cos(\theta) = \frac{a}{|(a, b)|} \text{ and } \sin(\theta) = \frac{b}{|(a, b)|} \right\}$$

Proposition 4.2.4

The following are true regarding the argument.

- $\arg(zw) = \arg(z) + \arg(w) = \{\theta + \phi \mid \theta \in \arg(z), \phi \in \arg(w)\}$
- $\arg(\bar{z}) = -\arg(z)$

Lemma 4.2.5

Let $z \in \mathbb{C}$ be a complex number. Then there exists a unique real number $\theta \in \mathbb{R}$ such that $\theta \in \arg(z)$ and $-\pi < \theta \leq \pi$.

Definition 4.2.6: Principal Argument

Define the principal argument function $\text{Arg} : \mathbb{C} \rightarrow \mathbb{R}$ to be the function sending $z \in \mathbb{C}$ to the unique real number $\text{Arg}(z) \in \mathbb{R}$ such that $-\pi < \text{Arg}(z) \leq \pi$ and $\text{Arg}(z) \in \arg(z)$.

Lemma 4.2.7

Let $z \in \mathbb{C}$ be a complex number. Then

$$\arg(z) = \{\text{Arg}(z) + 2\pi k \mid k \in \mathbb{Z}\}$$

Definition 4.2.8: Polar Form

Let $z \in \mathbb{C}$ be a complex number. Define the polar form of z to be the expression

$$z = |z| (\cos(\text{Arg}(z)) + \sqrt{-1} \sin(\text{Arg}(z)))$$

Proposition 4.2.9

Suppose that $z = r(\cos(\theta) + i \sin(\theta))$ and $w = s(\cos(\phi) + i \sin(\phi))$.

- $zw = rs(\cos(\theta + \phi) + i \sin(\theta + \phi))$
- $\frac{1}{z} = \frac{1}{r}(\cos(-\theta) + i \sin(-\theta))$
- $\frac{z}{w} = \frac{r}{s}(\cos(\theta - \phi) + i \sin(\theta - \phi))$
- $\bar{z} = r(\cos(-\theta) + i \sin(-\theta))$

4.3 Roots of Complex Numbers**Definition 4.3.1: n th Roots**

Let $w \neq 0$ be a complex number and n a positive integer. A number z is called the n th root of w if and only if $z^n = w$.

Theorem 4.3.2: De Moivre's Theorem

Suppose that $r \in \mathbb{Q}$. Then $(\cos \theta + i \sin \theta)^r = \cos(r\theta) + i \sin(r\theta)$

Theorem 4.3.3: Roots of Unity

Suppose that $z = re^{i\theta}$. Then the n th roots of z are

$$r^{\frac{1}{n}} \left[\cos \left(\frac{(\theta + 2\pi k)i}{n} \right) + i \sin \left(\frac{(\theta + 2\pi k)i}{n} \right) \right]$$

where $k = 0, 1, \dots, n-1$.
