1 Excisive Functors between Spaces

1.1 Homotopy Pushouts and Homotopy Pullbacks

Work in category CGWH all spaces pointed Σ = reduced suspension Cubical: all spaces assumed well-pointed (1.1.5 cubical) homotopy colimits should be as 8.2.14 (since well based then unpointed homotopy pullbacks is homotopy equivalent to pointed homotopy pullback)

Let me begin by slightly rephrasing what we learned in classical algebraic topology. Recall that if X is a space and $X = A \cup B$ are two open sets, then

$$\begin{array}{ccc} A \cap B & \hookrightarrow & A \\ \downarrow & & \downarrow \\ B & \hookrightarrow & X \end{array}$$

is a pushout in **Spaces**.

- Recall that amalgamated products of groups is precisely the pushout in **Grps** (when the two maps are embeddings). The Seifert-Van Kampen theorem then says that if $A \cap B$ is non-empty, then $\pi_1 : \mathbf{Spaces} \rightarrow \mathbf{Grp}$ sends pushouts to pushouts.
- If we upgrade the fundamental group π_1 into the fundamental groupoid Π_1 developed by Brown, again $\Pi_1 : \mathbf{Spaces} \rightarrow \mathbf{Spaces} \rightarrow \mathbf{Grpoids}$ sends pushouts to pushouts, without the assumption of connectedness of $A \cap B$, and removing the dependence of the base point. (6.7.2 R.Brown)
- Applying the singular homology functor does not give a pushout, nor a pullback, but gives a long exact sequence in homology which is useful for computation.
- Similarly, applying the singular cohomology functor gives a useful computational skill.

When we say that X is a pushout of A and B along $A \cap B$, we mean that X is built by the piece A and B . The Mayer-Vietoris theorem is the prime example of why we care about this. It says that computing the homology of parts of the space can recover homological information of the overall space. This is similar for the Seifert-van Kampen theorem. But in general, homotopy groups do not enjoy any theorems reminiscent to these properties, unless we are given (co)fibrations in which case there are indeed long exact sequences.

It is natural to look for conditions to relax so that we obtain similar results. The approach that algebraic topologists takes considers the following viewpoint: Most of the invariants in algebraic topology detect differences up to homotopy equivalence, but pushouts and pullbacks are more rigid than homotopy equivalence:

- Their universal properties guarantee that they are unique up to homeomorphism.
- Pushouts and pullbacks are determined by three spaces and two maps. But if we supply homotopy equivalent spaces then the pushout / pullback is not homotopy equivalence.

This means that pushouts and pullbacks (and in general arbitrary limits and colimits!) are quite incompatible with homotopies.

Example 1.1.1

Consider the following commutative diagram:

$$\begin{array}{ccccc} * & \longleftarrow & S^n & \hookrightarrow & D^{n+1} \\ \downarrow & & \text{id} \downarrow & & \downarrow * \\ * & \longleftarrow & S^n & \longrightarrow & * \end{array}$$

While all the vertical arrows are weak equivalences, the induced map of pushouts is given by $S^{n+1} \rightarrow *$ which is clearly not a weak equivalence. (dduggar0 (refer)

Therefore we concern ourselves with a homotopy invariant version of this concept. The ordinary pushouts and pullbacks are unique up to homeomorphism. We can explicitly define a set and its topology and show that it satisfies a universal property. We take a similar approach here and first introduce a model for homotopy pushouts.

Definition 1.1.2: The Standard Homotopy Pushout

Let $X, Y, Z \in \mathbf{CGWH}$ be spaces. Let $f : Z \rightarrow X$ and $g : Z \rightarrow Y$ be maps. Define the standard homotopy pushout of f and g to be the quotient space

$$\mathrm{hocolim}(X \xleftarrow{f} Z \xrightarrow{g} Y) = \frac{X \amalg (Z \times I) \amalg Y}{\sim}$$

where \sim is the equivalence relation generated by $f(z) \sim (z, 0)$ and $g(z) \sim (z, 1)$ for $z \in Z$.

Remember that we want our new pushout to be a homotopy invariant, not a homeomorphic invariant. Any homeomorphic spaces has one unique way of writing it down set theoretically, but homotopy equivalent spaces are not determined by its set theoretic representation. Given an arbitrary square in **Spaces**, we also want to know how to compare whether the square exhibits a homotopy pushout. In particular, we use the standard model as an anchor for comparison.

Definition 1.1.3: The Canonical Map of Homotopy Pushouts

Let $X, Y, Z \in \mathbf{CGWH}$ be spaces. Let $f : Z \rightarrow X$ and $g : Z \rightarrow Y$ be maps. Define the canonical map of the homotopy pushout of the diagram to be the map

$$s : \mathrm{hocolim}(X \xleftarrow{f} Z \xrightarrow{g} Y) \rightarrow \mathrm{colim}(X \xleftarrow{f} Z \xrightarrow{g} Y)$$

given by the formula

$$u \mapsto \begin{cases} u & \text{if } u \in X \\ f(z) = g(z) & \text{if } u = (z, t) \in Z \times I \\ u & \text{if } u \in Y \end{cases}$$

Definition 1.1.4: The Standard Homotopy Pullback

Let $X, Y, Z \in \mathbf{CGWH}$ be spaces. Let $f : X \rightarrow Z$ and $g : Y \rightarrow Z$ be maps. Define the standard homotopy pullback of f and g to be the subspace

$$\mathrm{holim}(X \xrightarrow{f} Z \xleftarrow{g} Y) = \{(x, \alpha, y) \in X \times \mathrm{Map}(I, Z) \times Y \mid \alpha(0) = f(x), \alpha(1) = g(y)\}$$

Definition 1.1.5: The Canonical Map of Homotopy Pullbacks

Let $X, Y, Z \in \mathbf{CGWH}$ be spaces. Let $f : X \rightarrow Z$ and $g : Y \rightarrow Z$ be maps. Define the canonical map from the pullback to the homotopy pullback

$$c : \lim(X \xrightarrow{f} Z \xleftarrow{g} Y) \rightarrow \mathrm{holim}(X \xrightarrow{f} Z \xleftarrow{g} Y)$$

to be given by $(x, y) \mapsto (x, e_{f(x)=g(y)}, y)$ where e refers to the constant loop at $f(x) = g(y)$.

Proposition 1.1.6

Let $X, Y, Z \in \mathbf{CGWH}$ be spaces. Let $f : X \rightarrow Z$ and $g : Y \rightarrow Z$ be maps. Then there is a homeomorphism

$$\lim(X \xrightarrow{f} Z \xleftarrow{g} Y) \cong \mathrm{holim}(X \xrightarrow{f} Z \xleftarrow{g} Y)$$

given by the map $(x, (y, \gamma)) \mapsto (x, \gamma, y)$.

Definition 1.1.7: Homotopy Pushout Squares

Let $W, X, Y, Z \in \mathbf{CGWH}$ be spaces such that there is a (not necessarily commutative) diagram

$$\begin{array}{ccc} W & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X & \longrightarrow & Z \end{array}$$

- We say that the square is a homotopy pushout square if the map

$$\beta : \operatorname{hocolim}(X \xleftarrow{f} W \xrightarrow{g} Y) \xrightarrow{s} \operatorname{colim}(X \xleftarrow{f} W \xrightarrow{g} Y) \rightarrow Z$$

is a weak equivalence.

- We say that the diagram is k -cocartesian if β is k -connected.

Definition 1.1.8: Homotopy Pullback Squares

Let $W, X, Y, Z \in \mathbf{CGWH}$ be spaces such that there is a (not necessarily commutative) diagram

$$\begin{array}{ccc} W & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X & \longrightarrow & Z \end{array}$$

- We say that the diagram is a homotopy pullback if the map

$$\alpha : W \rightarrow \operatorname{lim}(X \xrightarrow{f} Z \xleftarrow{g} Y) \xrightarrow{c} \operatorname{holim}(X \xrightarrow{f} Z \xleftarrow{g} Y)$$

is a weak equivalence.

- We say that the diagram is k -cartesian if α is k -connected.

It may appear weird that we require a weak equivalence instead of a homotopy equivalence. But it turns out this is the correct notion because of the following.

Theorem 1.1.9: The Matching Lemma

Suppose that we have a commutative diagram of spaces

$$\begin{array}{ccccc} X & \xrightarrow{f} & Z & \xleftarrow{g} & Y \\ e_X \downarrow & & e_Z \downarrow & & \downarrow e_Y \\ X' & \xrightarrow{f'} & Z' & \xleftarrow{g'} & Y' \end{array}$$

in \mathbf{CGWH} . Define the map

$$\phi_{X',Z',Y'}^{X,Z,Y} : \operatorname{holim}(X \xrightarrow{f} Z \xleftarrow{g} Y) \rightarrow \operatorname{holim}(X' \xrightarrow{f'} Z' \xleftarrow{g'} Y')$$

by the formula $(x, \gamma, y) \mapsto (e_X(x), e_Z \circ \gamma, e_Y(y))$. Then the following are true.

- If each e_X, e_Y, e_Z are homotopy equivalences, then ϕ is a homotopy equivalence.
- If each e_X, e_Y, e_Z are weak equivalences, then ϕ is a weak equivalence.

Proof. We first prove the case for homotopy equivalence. Consider the following commutative diagram:

$$\begin{array}{ccccc}
X & \xrightarrow{f} & Z & \xleftarrow{g} & Y \\
\text{id}_X \downarrow & & \downarrow e_Z & & \downarrow \text{id}_Y \\
X & \xrightarrow{e_Z \circ f} & Z' & \xleftarrow{e_Z \circ g} & Y \\
e_X \downarrow & & \downarrow \text{id}_{Z'} & & \downarrow e_Y \\
X' & \xrightarrow{f'} & Z' & \xleftarrow{g'} & Y'
\end{array}$$

We prove that the homotopy pullback of the first row is homotopy equivalent to that of the second, and we prove that the homotopy pullback of the second row is homotopy equivalent to that of the third.

Since e_Z is a homotopy equivalence, we can find a homotopy inverse k for e_Z and a homotopy $H : Z \times I \rightarrow Z$ such that $H(-, 0) = \text{id}_Z$ and $H(-, 1) = k \circ e_Z$. Define a map

$$\rho : \text{holim}(X \xrightarrow{f} Z' \xleftarrow{g} Y) \rightarrow \text{holim}(X \xrightarrow{e_Z \circ f} Z \xleftarrow{e_Z \circ g} Y)$$

by the formula

$$(x, \gamma', y) \mapsto (x, H(f(x), -) * k(\gamma'(-)) * \overline{H(g(y), -)} : I \rightarrow Z, y)$$

where $*$ denotes concatenation of paths. The path concatenation is well defined because we have that $H(f(x), 1) = (k \circ e_Z \circ f)(x) = (k \circ \gamma')(0)$ and $k(\gamma'(1)) = k(e_Z(g(y))) = H(g(y), 1)$. This is well defined on the homotopy pullback because we have that

- $H(f(x), -) * k(\gamma'(-)) * \overline{H(g(y), -)}(0) = H(f(x), 0) = \text{id}_Z(f(x)) = f(x)$
- $H(f(x), -) * k(\gamma'(-)) * \overline{H(g(y), -)}(1) = H(g(y), 0) = \text{id}_Z(g(y)) = g(y)$

I claim that this map is the homotopy inverse to the map $\phi = \phi_{X,Y,Z'}^{X,Y,Z}$. We have that

$$\begin{aligned}
\rho(\phi(x, \gamma, y)) &= \rho(x, e_Z \circ \gamma, y) \\
&= (x, H(f(x), -) * k(e_Z(\gamma(-))) * \overline{H(g(y), -)}, y)
\end{aligned}$$

Now I claim that the middle path is homotopic to γ . For the first component of the concatenation, the path $H(f(x), t) : I \rightarrow Z$ can be contracted to $H(f(x), 0) = f(x) = \gamma(0)$ so you can homotope the traversal along $H(f(x), -)$ to the single point $f(x) = \gamma(0)$. For the third component of the concatenation, this is similar so we can homotope the traversal of $\overline{H(g(y), -)}$ to the single point $g(y) = \gamma(1)$. The middle part of the path is homotopic to γ because $k \circ e_Z$ is homotopic to id_Z . Thus we conclude. \square

Note: there is a similar result for pushouts.

We can compute some examples of homotopy pushouts and pullbacks.

Example 1.1.10

Homotopy fiber as homotopy pushout and homotopy pullback

Example 1.1.11

Let X be a pointed space. There is a unique map $X \rightarrow *$ to the terminal object in **Spaces**. The homotopy pushout of $* \leftarrow X \rightarrow *$ is given by

$$\text{hocolim}(* \leftarrow X \rightarrow *) = \frac{* \amalg (X \times I) \amalg *}{\sim}$$

where \sim is generated by $* \sim (x, 0)$ and $* \sim (x, 1)$. This is precisely the definition of suspension.

Similarly, there is a unique map $* \rightarrow X$ sending $*$ to the base point of X . The homotopy pullback of $* \rightarrow X \leftarrow *$ is given by

$$\begin{aligned} \operatorname{holim}(* \rightarrow X \leftarrow *) &= \{(*, \gamma, *) \in * \times \operatorname{Map}(I, X) \times * \mid \gamma(0) = * = \gamma(1)\} \\ &\cong \{\gamma \in \operatorname{Map}(I, X) \mid \gamma \text{ is a loop at the base point}\} \end{aligned}$$

This is precisely the definition of loop space.

Proposition 1.1.12

Consider the following (not necessarily commutative) square

$$\begin{array}{ccccc} X_1 & \longrightarrow & X_2 & \longrightarrow & X_3 \\ \downarrow & & \downarrow & & \downarrow \\ Y_1 & \longrightarrow & Y_2 & \longrightarrow & Y_3 \end{array}$$

in **CGWH**. Let the right square be a homotopy pullback square. Then the left square is a homotopy pullback if and only if the rectangle is a homotopy pullback square.

Proof.

□

(6.3.3 Arkhowitz)

Proposition 1.1.13

Let $W, X, Y, Z \in \mathbf{CGWH}$ be spaces such that there is a (not necessarily commutative) diagram

$$\begin{array}{ccc} W & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X & \longrightarrow & Z \end{array}$$

Then the following are true.

- If the square is a homotopy pullback, and $Y \rightarrow Z$ is a weak equivalence, then $W \rightarrow X$ is a weak equivalence.
- If $Y \rightarrow Z$ and $W \rightarrow X$ are weak equivalence, then the square is a homotopy pullback.

Proposition 1.1.14

Let $W, X, Y, Z \in \mathbf{CGWH}$ be spaces such that following is a (not necessarily commutative) square

$$\begin{array}{ccc} W & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X & \longrightarrow & Z \end{array}$$

Then the following are true.

- The square is a homotopy pullback if and only if for all $x \in X$, the map

$$\operatorname{hofiber}_x(W \rightarrow X) \rightarrow \operatorname{hofiber}_{f(x)}(Y \rightarrow Z)$$

is a weak equivalence.

- The square is k -cartesian if and only if for all $x \in X$, the map

$$\operatorname{hofiber}_x(W \rightarrow X) \rightarrow \operatorname{hofiber}_{f(x)}(Y \rightarrow Z)$$

is k -connected.

Proof. Begin with the homotopy pullback square

$$\begin{array}{ccc} \mathrm{holim}(X \rightarrow Z \leftarrow Y) & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X & \longrightarrow & Z \end{array}$$

We know that there is a homotopy pullback square given by

$$\begin{array}{ccc} \mathrm{holim}_y(g) & \longrightarrow & Y \\ \downarrow & & \downarrow g \\ * & \longrightarrow & X \longrightarrow Z \end{array}$$

We can view this as a homotopy pullback square where we consider the composition $\mathrm{holim}_y(g) \rightarrow * \rightarrow X$ as one single map. This gives a comparison of a homotopy pullback square with the standard homotopy pullback. Hence we obtain

$$\begin{array}{ccccc} \mathrm{holim}_y(g) & \longrightarrow & \mathrm{holim}(X \rightarrow Z \leftarrow Y) & \longrightarrow & Y \\ \downarrow & & \downarrow & & \downarrow g \\ * & \longrightarrow & X & \longrightarrow & Z \end{array}$$

By the above prp, we conclude that the square on the left is a homotopy pullback. By the same method, we can glue two more squares to obtain the diagram:

$$\begin{array}{ccccccc} \mathrm{holim}_y(\alpha) & \longrightarrow & \mathrm{holim}_y(f) & \longrightarrow & W & & \\ \downarrow & & \downarrow u & & \downarrow \alpha & & \\ * & \longrightarrow & \mathrm{holim}_y(g) & \longrightarrow & \mathrm{holim}(X \rightarrow Z \leftarrow Y) & \longrightarrow & Y \\ & & \downarrow & & \downarrow & & \downarrow g \\ & & * & \longrightarrow & X & \longrightarrow & Z \end{array}$$

If α is a weak equivalence, then since the top wide rectangle is a homotopy pullback we have $\mathrm{holim}_y(\alpha)$ is weakly equivalent to $*$. But the top left square is a homotopy pullback hence $\mathrm{holim}_y(f)$ is weakly equivalent to $\mathrm{holim}_y(g)$. Conversely, suppose that u is a weak equivalence. Since the top left square is a homotopy pullback, this implies that $\mathrm{holim}_y(\alpha)$ is weakly contractible for all y . In particular it is n -connected for all n . Then this implies that α is $(n+1)$ -connected for all n . Hence α is a weak equivalence. \square

Need: 3.7.29 (for Blakers-Massey)

Definition 1.1.15: Excisive Functors

Let $F : \mathbf{Spaces} \rightarrow \mathbf{Spaces}$ be a functor. We say that F is excisive if the following are true.

- F is a homotopy functor. This means that if f is a weak equivalence, then $F(f)$ is a weak equivalence.
- F is finitary. This means that if I is a filtered category and $X : I \rightarrow \mathbf{Spaces}$ is a diagram, then

$$\mathrm{hocolim}_{i \in I} F(X_i) \rightarrow F\left(\mathrm{hocolim}_{i \in I} X_i\right)$$

is a weak equivalence.

- F sends homotopy pushouts to homotopy pullbacks.

The finitary requirement ensures that the functor F is determined by its value on finite complexes. Then by taking homotopy colimits the value of F on spaces generated by colimits of finite complexes are determined. We will say something about this condition again in section 2.

A reasonable question might be to ask why excisive functors send homotopy pushouts to homotopy pullbacks instead to homotopy pushouts. Intuitively, pushouts are how we assemble spaces using smaller pieces. But interestingly enough, homotopy groups work better with homotopy pullbacks rather than homotopy pushouts.

Theorem 1.1.16

LES of homotopy groups <https://math.stackexchange.com/questions/1262049/long-exact-sequence-of-homotopy-groups-pi-n-for-a-pointed-homotopy-pullback-s> 5.6.9 Martin Arkowitz

1.2 The Failure of the Identity Functor to be Excisive

It is natural to ask what kinds of functors are excisive. Instead of giving an example of an excisive functor, allow me to give an example of a functor that is not excisive. There are two reasons for this. The main theorem - Blakers-Massey theorem will assist us in giving a plethora of excisive functors. Moreover, it demonstrates the possibly simplest functor in existence - the identity functor is not excisive.

Blakers-Massey theorem itself is a powerful theorem that implies the connectivity bounds in the Freudenthal suspension theorem. Before the main theorem, we must present preparatory definitions and lemmas, and then prove a special case of the theorem, and finally generalize it to the arbitrary case. Let me first give the statement of the main theorem.

Theorem 1.2.1: Blakers-Massey Theorem

Let $X_0, X_1, X_2, X_{12} \in \mathbf{CGWH}$ be spaces such that the square

$$\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_{12} \end{array}$$

is a homotopy pushout. Suppose the map $X_0 \rightarrow X_i$ is k_i -connected for $i = 1, 2$. Then the diagram is $(k_1 + k_2 - 1)$ -cartesian. Explicitly, this means that

$$\alpha : X_0 \rightarrow \operatorname{holim}(X_1 \rightarrow X_{12} \leftarrow X_2)$$

is $(k_1 + k_2 - 1)$ -connected.

Firstly, recall that a square is a homotopy pullback if the map α above is n -connected for all $n \in \mathbb{N}$. The theorem implies that the identity functor is not excisive because after giving connectedness assumptions on maps in the square, we only get an upper bound of the connectedness of α , which means that the identity functor is excisive up to a certain dimension.

Definition 1.2.2: (Degenerative) Cubes

Let $a = (a_1, \dots, a_n) \in \mathbb{R}^n$. Let $\delta > 0$. Let $L \subseteq \{1, \dots, n\}$. A cube in \mathbb{R}^n is a set of the form

$$W = W(a, \delta, L) = \{x \in \mathbb{R}^n \mid a_i \leq x_i \leq a_i + \delta \text{ for } i \in L \text{ and } x_i = a_i \text{ for } i \notin L\}$$

The notation is making the object more complicated than what it should look like. $a \in \mathbb{R}^n$ refers to the bottom left coordinate of the cube. δ is the length of the cube and L refers to the number of non-degenerate faces of the cube. In particular, any cube in \mathbb{R}^n is homeomorphic to the standard cube I^k for some $k \leq n$.

- When $n = 3$, $W(0, 1, \{1, 2\})$ is the unit square on the xy -plane.

- When $n = 3$, $W(0, 1, \{1, 2, 3\})$ is the unit cube.
- When $n = 4$, $W(0, 1, \{1, 2, 3\})$ is the unit cube with nonzero first three coordinates and zero otherwise.

Definition 1.2.3: Special Sub-cube of a Cube

Let $W = W(a, \delta, L)$ be a cube in \mathbb{R}^n . Let $j = 1$ or 2 . Suppose that $1 \leq p \leq |L|$. Define

$$K_p^j(W) = \left\{ (x_1, \dots, x_n) \in W \mid \frac{\delta(j-1)}{2} + a_i < x_i < \frac{\delta j}{2} + a_i \text{ for at least } p \text{ values of } i \in L \right\}$$

Again the notation is making the object more complicated. Taking $W = W(0, 1, \{1, 2, 3\}) = I^3$ in \mathbb{R}^3 , we have

- $K_3^1(W) = W(0, 1/2, \{1, 2, 3\})$ is one eighth of the cube I^3 with bottom left corner at the origin.
- $K_3^2(W) = W((1/2, 1/2, 1/2), 1/2, \{1, 2, 3\})$ is one eighth of the cube I^3 with bottom left corner at $(1/2, 1/2, 1/2)$
- $K_2^1(W)$ allows for one coordinate to go beyond the bottom left one eighth of the cube, and is the union four of the $1/8$ -sub-cubes that are adjacent to the xy -plane, the yz -plane and the xz -plane.
- $K_1^1(W)$ allows for two coordinate to go beyond the bottom left one eighth of the cube, and is equal to $W \setminus K_3^2(W)$.
- $K_0^1(W)$ allows for all coordinate to go beyond the bottom left one eighth of the cube, so the condition becomes vacuous and is equal to W .

Summarizing, we think of $K_p^j(W)$ as follows. Subdivide the $|L|$ -dimensional cube into $2^{|L|}$ sub-cubes of equal volume. K_p^1 is the union of a number of sub-cubes closest to the bottom left sub-cube. K_p^2 is the union of a number of sub-cubes closed to the upper right sub-cube.

Lemma 1.2.4

Let Y be a space. Let $B \subseteq Y$ be a subspace of Y . Let $W = W(a, \partial, L)$ be a cube in \mathbb{R}^n . Let $f : W \rightarrow Y$ be a map. Let $j = 1$ or 2 . Suppose that there exists some $p \leq |L|$ such that

$$f^{-1}(B) \cap C \subset K_p^j(C)$$

for all cubes $C \subset \partial W$. Then there exists a map $g : W \rightarrow Y$ such that $g \stackrel{\partial W}{\simeq} f$ and

$$g^{-1}(B) \subset K_p^j(W)$$

Proof. (Proof by Munson in Cubical Homotopy Theory) Firstly, notice that any cube W is homeomorphic to I^n for some n , so we can just prove the statement for when $W = I^n$. In this case, our parameters of the cube is given by $I^n = W(a = 0, \delta = 1, L = \{1, \dots, n\})$ and our $K_p^j(W)$ is given by

$$K_p^j(W) = \left\{ (x_1, \dots, x_n) \in C \mid \frac{j-1}{2} < x_i < \frac{j}{2} \text{ for at least } p \text{ values of } i \in \{1, \dots, n\} \right\}$$

Let p_j be the center of the sub-cube $[\frac{j-1}{2}, \frac{j}{2}]^n$ inside I^n for $j = 1, 2$. Let R be a ray with starting point p_j . Let $P(R, p_j)$ be the intersection of R and $\partial[\frac{j-1}{2}, \frac{j}{2}]^n$. Let $Q(R, p_j)$ be the intersection of R and ∂I^n . By construction, the points p_j , $P(R, p_j)$ and $Q(R, p_j)$ are collinear with $P(R, p_j)$ always being the mid point and $P(R, p_j)$ is possibly equal to $Q(R, p_j)$. Being a line, we can define a linear homotopy from the line $[p_j, P(R, p_j)]$ to the line $[p_j, Q(R, p_j)]$ that fixes the point p_j and sends $P(R, p_j)$ to $Q(R, p_j)$. Denote the homotopy by $h(y, t)$ for $y \in [p_j, P(R, p_j)]$ and t the time variable.

Now we can define a homotopy $H_j : I^n \times I \rightarrow I^n$ as follows: For each $y \in I^n$, there exists a unique ray R starting at p_j and passing through y . Then we obtain a homotopy h from $[p_j, P(R, p_j)]$ to $[p_j, Q(R, p_j)]$ as above. Define $H(y, t) = h(y, t)$. It is clear that $H_j(q, 1) = q$ for all $q \in \partial I^n$ so that H_j is a homotopy from the identity, relative to the boundary ∂I^n .

Let $g = f \circ H_j(-, 1)$. From the properties of the homotopy H_j , we notice that $f \circ H_j : I^n \times I \rightarrow Y$ is a homotopy from $f \circ H(-, 0) = f \circ \text{id} = f$ to $f \circ H(-, 1) = g$, relative to the boundary ∂I^n . Thus we now have a homotopy from f to a map g relative to the boundary. It remains to show that $g^{-1}(B) \subset K_p^j(C)$.

Let $z = (z_1, \dots, z_n) \in g^{-1}(B)$. If $z \in [\frac{j-1}{2}, \frac{j}{2}]^n$ then clearly $z \in K_p^j(C)$ is true. So suppose instead that $z = (z_1, \dots, z_n) \in g^{-1}(B)$ satisfies the fact that either $z_a \geq \frac{j}{2}$ or $z_b \leq \frac{j-1}{2}$ for $1 \leq a, b \leq n$. Let R be the ray from p_j passing through z . Then the condition on z means that $z \in [P(R, p_j), Q(R, p_j)]$. Hence under the homotopy H , z is mapped to ∂I^n . But ∂I^n is a union $n - 1$ dimensional faces of I^n which are cubes. So $H(z, 1)$ lies in some cube $C \subseteq \partial I^n$. By construction of g , $g(z) = f(H(z, 1))$ and $g(z) \in B$ implies that $H(z, 1) \in f^{-1}(B)$. Then $H(z, 1) \in f^{-1}(B)$ and $H(z, 1) \in C$ implies that

$$H(z, 1) \in f^{-1}(B) \cap C \subseteq K_p^j(C)$$

by the assumption on f . Write $H(z, 1) = (w_1, \dots, w_n) \in \partial I^n$. This means that $\frac{j-1}{2} < w_i < \frac{j}{2}$ for at least p of the coordinates of $H(z, 1)$.

Now the ray starting at p_j and passing through z is parametrized by the line $p_j + t(z - p_j)$ for $t \geq 0$. Since $H(z, 1)$ lies behind the two points z and p_j , we can write $H(z, 1) = p_j - t_0(z - p_j)$ for some $t_0 \geq 1$. By definition, p_j is the point given in coordinates by $(\frac{2j-1}{4}, \dots, \frac{2j-1}{4})$. Hence the i th coordinate of $H(z, 1)$ can be written as

$$w_i = \frac{2j-1}{4} + t_0 \left(z_i - \frac{2j-1}{4} \right)$$

Recall that in the previous paragraph we found that $\frac{j-1}{2} < w_i < \frac{j}{2}$ for at least p of the coordinates of $H(z, 1)$. Substituting w_i into the inequality and simplifying gives

$$-\frac{1}{4t_0} + \frac{2j-1}{4} < z_i < \frac{1}{4t_0} + \frac{2j-1}{4}$$

Since $t_0 \geq 1$, we get

$$-\frac{1}{4} + \frac{2j-1}{4} < -\frac{1}{4t_0} + \frac{2j-1}{4} < z_i < \frac{1}{4t_0} + \frac{2j-1}{4} < \frac{1}{4} + \frac{2j-1}{4}$$

The leftmost and rightmost terms bound z_i between $\frac{j-1}{2}$ and $\frac{j}{2}$ for at least p amount of coordinates z_i of z . Hence $z \in K_p^j(C)$. This completes the proof. \square

Lemma 1.2.5

Let X be a space. Let $X_0, X_1, X_2 \subseteq X$ be subspaces of X such that

$$X = X_1 \cup X_2$$

and $X_0 = X_1 \cap X_2$ is non-empty. Assume that for each $i = 1, 2$, (X_i, X_0) is k_i -connected with $k_i \geq 0$. Let $f : I^n \rightarrow X$ be a map. Let

$$I^n = \bigcup_k W_k$$

be the decomposition of I^n into cubes W_k such that $f(W_k) \subseteq X_i$ for one of $i = 0, 1, 2$ by the

Lebesgue covering lemma. Then there exists a homotopy

$$H : I^n \times I \rightarrow X$$

such that the following are true.

- $f(-) = H(-, 0)$
- If $f(W) \subset X_i$, then $H(W, t) \subset X_i$ for all $t \in I$.
- If $f(W) \subset X_0$, then $H(W, t) = f(W)$ for all $t \in I$.
- If $f(W) \subset X_i$, then $((H(-, 1))^{-1}(X_i \setminus X_0)) \cap W \subset K_{k_i+1}^i(W)$.

Proof. Let C^d be the union of all cubes of dimension $\leq d$. We induct on d , the existence of such a homotopy $H : C^d \times I \rightarrow X$ that holds the required conditions true for all cubes W with dimension $\leq d$.

We first construct the homotopy for all cubes of dimension 0. When $\dim(W) = 0$, there are two cases:

- If $f(W) \subset X_0$, define $H|_{W \times I}$ by $H(w, t) = f(w)$
- If $f(W) \subset X_j$ and $f(W) \not\subset X_i$ for $1 \leq i \neq j \leq 2$, (X_j, X_0) is $(k_j \geq 0)$ -connected implies that there exists a path $\gamma : I \rightarrow X$ from $f(W)$ to a point in X_0 . Define $H|_{W \times I}$ by $H(w, t) = \gamma(t)$ (again $W = \{w\}$ is a one point set).

Thus we now have a well defined map $H : C^0 \times I \rightarrow X$. We need to show that this map satisfies the required conditions.

- For each $z \in C^0$, either $H(z, 0) = f(z)$ from the first case or $H(z, 0) = \gamma(0) = f(z)$.
- If $f(W) \subset X_i$, then by construction $H(W, t) \subset X_i$ from the second case.
- If $f(W) \subset X_0$, then $H(W, t) = f(W)$ by the first case.
- $K_{k_i+1}^i(W) = \{w\}$ is a one point set and $(H(-, 1))^{-1}(X_i \setminus X_0) \cap W \subseteq W$ means that this condition is satisfied.

Now H is built on three pieces: the union of cubes landing in X_i for $i = 0, 1, 2$. The second and third conditions guarantee that each of the three pieces define a homotopy on each piece respectively. Since $\partial W \hookrightarrow W$ is a cofibration, we can extend these pieces of homotopy from 0-dimensional cubes to 1-dimensional. Recursively we are able to define a homotopy for all cubes of all dimensions inside I^n that satisfy the first three conditions.

Therefore now we can invoke the inductive hypothesis, so that there exists a homotopy from f so that the new function satisfy all our required conditions for all cubes of dimension $< d$. With abuse of notation, call the restriction of our newly acquired function to C^{d-1} also by the name f . Let W be a cube of dimension d .

- If $f(W) \subseteq X_0$, define $H|_{W \times I}$ by $H(w, t) = f(w)$
- If $f(W) \subset X_1$ and $f(W) \not\subset X_2$ and $\dim(W) = d \leq k_1$, (X_j, X_0) is $(k_j \geq 0)$ -connected implies there exists a homotopy $K : W \times I \rightarrow X$ from f relative to ∂W such that $K(W, 1) \subseteq X_0$. Define $H|_{W \times I}$ by $H = K$.
- If $f(W) \subset X_1$ and $f(W) \not\subset X_2$ and $\dim(W) = d > k_1$, then by induction we have

$$f^{-1}(X_1 \setminus X_0) \cap W' \subset K_d^1(W') \subset K_{k_1+1}^1(W')$$

for all $W' \subset \partial W$ (induction is applicable since $\dim(W') < \dim(W)$). By the above lemma, there exists a map $g : W \rightarrow X$ such that g and f are homotopic relative to ∂W such that $g^{-1}(X_1 \setminus X_0) \subset K_{k_1+1}^1(W)$. Call this homotopy from f to g by

$R : W \times I \rightarrow X$. Then we define $H|_{W \times I}$ by $H = R$.

(WLOG the cases where X_1 is swapped with X_2 and k_1 is swapped with k_2 and $K_p^1(W)$ is swapped with $K_p^2(W)$ in the last two sub-cases has a symmetrical argument). Finally we show that our required conditions are satisfied.

- In all cases, $H(-, 0) = f$ as one can immediately see.
- The second condition holds for all cubes of dimension $< d$ by inductive hypothesis. It also holds for our first and second case since $X_0 \subset X_1, X_2$. For the third case, H is a homotopy relative to ∂W . Since by induction hypothesis $f(\partial W) \subseteq X_1$, we also have $g(\partial W) \subseteq X_1$. Since g is continuous then $H(W, 1) = g(W) \subseteq X_1$.

- The third condition holds for all cubes of dimension $< d$ by inductive hypothesis, and holds true for all cubes of dimension d by the first case.
 - The fourth condition holds true by our argument in the third case, and is vacuously true in the second case since $H(W, 1) \subseteq X_0$ implies that $(H(-, 1))^{-1}(X_1 \setminus X_0) = \emptyset$.
- Thus the proof is complete. \square

We can now prove a weaker version of Blakers-Massey theorem.

Proposition 1.2.6

Let X be a space. Let e^{d_i} be a cell of dimension d_i for $i = 1, 2$. Then the following diagram

$$\begin{array}{ccc} X & \longrightarrow & X \cup e^{d_1} \\ \downarrow & & \downarrow \\ X \cup e^{d_2} & \longrightarrow & X \cup e^{d_1} \cup e^{d_2} \end{array}$$

given by inclusion maps is $(d_1 + d_2 - 3)$ -cartesian.

Proof. (Proof is by Munson in Cubical Homotopy Theory) Let $p_1 \in e^{d_1}$ and $p_2 \in e^{d_2}$ be interior points. Since $X \cup e^{d_2}$ is weakly equivalent to $X \cup e^{d_1} \cup e^{d_2} \setminus \{p_1\}$ by inclusion (and similarly for $X \cup e^{d_1}$), the above square admits a weak equivalence to the following square:

$$\begin{array}{ccc} X \cup e^{d_1} \cup e^{d_2} \setminus \{p_1, p_2\} & \hookrightarrow & X \cup e^{d_1} \cup e^{d_2} \setminus \{p_2\} \\ \downarrow & & \downarrow \\ X \cup e^{d_1} \cup e^{d_2} \setminus \{p_1\} & \hookrightarrow & X \cup e^{d_1} \cup e^{d_2} \end{array}$$

Let $Y = X \cup e^{d_1} \cup e^{d_2}$. By thm??? to show that the square is $(d_1 + d_2 - 3)$ -cartesian is the same as showing the map

$$\mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) \rightarrow \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y)$$

is $(d_1 + d_2 - 3)$ -cartesian. Let

$$C = \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y \setminus \{p_2\}) \simeq *$$

Now the intersections below can be calculated to give

$$C \cap \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) = \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1, p_2\})$$

and

$$C \cap \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) = \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y \setminus \{p_2\}) \simeq *$$

(because C and the homotopy fibers are all subspaces of $Y \times \mathrm{Map}(I, Y)$). By thm??? we conclude that the square

$$\begin{array}{ccc} C \cap \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) & \hookrightarrow & \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) \\ \downarrow & & \downarrow \\ C & \hookrightarrow & C \cup \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) \end{array}$$

is a homotopy pullback. Since the left two terms are contractible, it is a weak equivalence. By thm??? we conclude that the map on the right is a weak equivalence. Similarly, we can consider the diagram

$$\begin{array}{ccc} C \cap \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) & \hookrightarrow & \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) \\ \downarrow & & \downarrow \\ C & \hookrightarrow & C \cup \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) \end{array}$$

which is a homotopy pullback. And the fact that the terms on the left are contractible imply that the map on the right (which is in fact equal)

$$\mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) \xrightarrow{\cong} \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y)$$

is a weak equivalence by the same theorem. We now have a chain of maps

$$\begin{array}{ccc} \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) & \xrightarrow{\text{weak eq.}} & C \cup \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}) \\ & \nearrow & \\ C \cup \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) & \xrightarrow{\text{weak eq.}} & \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y) \end{array}$$

where the middle map is inclusion. It remains to show that the middle map is $(d_1 + d_2 - 3)$ -connected. This is the same as showing that the pair

$$(C \cup \mathrm{hofiber}_y(Y \setminus \{p_2\} \rightarrow Y), C \cup \mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\}))$$

is $(d_1 + d_2 - 3)$ -connected.

To simplify notations let us write the pair as (A, B) . Let $\phi : (I^n, \partial I^n) \rightarrow (A, B)$ be a map. Recall that $A = \{(x, \phi) \in Y \times \mathrm{Map}(I, Y) \mid \phi(0) = y, \phi(1) = x\}$. The first variable is determined by the end point of ϕ so giving a map $I^n \rightarrow A$ is the same as giving a map $I^n \rightarrow \mathrm{Map}(I, Y)$ for which all paths in the image has starting point y and ending point in $Y \setminus \{p_2\}$. By the hom-product adjunction, this is equivalent to giving a map $\psi : I^n \times I \rightarrow Y$ such that $\psi(z, 0) = y$ is the base point and $\psi(z, 1) \in Y \setminus \{p_2\}$. Similarly, we can consider the map $\phi : \partial I^n \rightarrow B$ and deduce that $\phi(z)$ is a path lying entirely in the codomain of the map of the homotopy fiber $C = \mathrm{hofib}_y(Y \setminus \{p_2\} \rightarrow Y \setminus \{p_2\})$ or it is a path lying entirely in the codomain of the map of the homotopy fiber $\mathrm{hofiber}_y(Y \setminus \{p_1, p_2\} \rightarrow Y \setminus \{p_1\})$. By the same adjunction we conclude that our ψ above must also satisfy for any fixed $z \in \partial I^n$, $\psi(z, t)$ lies entirely in either $Y \setminus \{p_1\}$ or $Y \setminus \{p_2\}$ (and conversely these information give a map $(I^n, \partial I^n) \rightarrow (A, B)$ by the adjunction).

To summarize: we have a map

$$\psi : I^n \times I \rightarrow Y$$

such that

- $\psi(z, 0) = y$ is the base point for all $z \in I^n$.
- $\psi(z, 1) \in Y \setminus \{p_2\}$ for all $z \in I^n$.
- For any fixed $z \in \partial I^n$, $\psi(z, t)$ lies entirely in $Y \setminus \{p_1\}$ or $Y \setminus \{p_2\}$ for varying t .

The goal is to make a homotopy from ψ to a map whose third condition holds for any $z \in I^n$ when $n \leq d_1 + d_2 - 3$. Then passing through the adjunction again we see that our original map $(I^n, \partial I^n) \rightarrow (A, B)$ is homotopic to the constant map as required. Apply 5.1.4 to obtain a homotopy $H : I^n \times I \times I \rightarrow Y$ from ψ to a new map $\eta : I^n \times I \rightarrow Y$, such that we have a decomposition of $I^n \times I$ into cubes W and the following are true.

1. $\psi(W) \subset Y \setminus \{p_2\}$ implies $H(W, r) \subset Y \setminus \{p_2\}$ for all $r \in I$.
2. $\psi(W) \subset Y \setminus \{p_1\}$ implies $H(W, r) \subset Y \setminus \{p_1\}$ for all $r \in I$.
3. $\psi(W) \subset Y \setminus \{p_1, p_2\}$ implies $H(W, r) = \psi(W)$ for all $r \in I$.
4. $\psi(W) \subset Y \setminus \{p_2\}$ then $(H(-, 1)^{-1}(\{p_1\})) \cap W \subset K_{d_1}^1(W)$
5. $\psi(W) \subset Y \setminus \{p_1\}$ then $(H(-, 1)^{-1}(\{p_2\})) \cap W \subset K_{d_2}^2(W)$

We claim that $H(z, t, r)$ satisfies the three bullet points for all fixed r .

Firstly, we already know that $\psi(z, 0) = y$ is the base point for all $z \in I^n$. So for all cubes $W \subseteq I^n \times \{0\}$, we have $\psi(W) = \{y\} \subset Y \setminus \{p_1, p_2\}$. By 3., we conclude that $H(W, r) = \psi(W) = \{y\}$. Secondly, we know that $\psi(z, 1) \in Y \setminus \{p_2\}$ for all $z \in I^n$. So for all cubes $W \subseteq I^n \times \{1\}$, we have $\psi(W) \subset Y \setminus \{p_2\}$. By 1., we conclude that $H(W, r) \subset Y \setminus \{p_2\}$ for all $r \in I$. Finally, according to the third bullet point, $\psi(z, I)$ lies entirely in $Y \setminus \{p_1\}$ or $Y \setminus \{p_2\}$ for $z \in \partial I^n$ WLOG lets say it lies entirely in $Y \setminus \{p_i\}$. Choose cubes W_1, \dots, W_k in

the decomposition of $I^n \times I$ so that it forms a minimal cover for $\{z\} \times I \subset W_1 \cup \dots \cup W_k$. By definition of the decomposition, these cubes firstly contain at least one point in $\{z\} \times I$, and $\psi(\{z\} \times I) \subset Y \setminus \{p_j\}$ implies that $\psi(W_1), \dots, \psi(W_k) \subset Y \setminus \{p_j\}$. By 1., we conclude that $H(W_1, r), \dots, H(W_k, r) \subset Y \setminus \{p_j\}$ so that $H(W_1 \cup \dots \cup W_k, r) \subset Y \setminus \{p_j\}$.

It remains to show that $\eta(-, -) = H(-, -, 1)$ satisfies the stronger condition of the third bullet point as desired. Let $n \leq d_1 + d_2 - 3$. We want to show that $\eta(z, I) \subset Y \setminus \{p_j\}$ for some j . I claim that this is equivalent to saying

$$\text{proj}(\eta^{-1}(\{p_1\})) \cap \text{proj}(\eta^{-1}(\{p_2\})) = \emptyset$$

where proj is the projection to the first coordinate. Indeed if $\eta(z, I)$ always lie inside one of $Y \setminus \{p_j\}$, $j = 1, 2$, then $\text{proj}(\eta^{-1}(\{p_1\})) = \{z \in I^n \mid \eta(z, I) \subset Y \setminus \{p_1\}\}$ and similarly for the other projection so that their intersection is empty. Conversely if one of $\eta(z, I)$ does not entirely lie in $Y \setminus \{p_2\}$ then the intersection is non-empty.

So it suffices to prove that the intersection given above is empty. So suppose it is non-empty with an element z_0 . Then there exists $t_1, t_2 \in I$ such that $\eta(z_0, t_1) \in Y \setminus \{p_2\}$ and $\eta(z_0, t_2) \in Y \setminus \{p_1\}$. Choose cubes $W_1 = W(a_1, \delta_1, L_1)$, $W_2 = W(a_2, \delta_2, L_2)$ in the given decomposition of $I^n \times I$ so that $(z_0, t_1) \in W_1$ and $(z_0, t_2) \in W_2$. By 4. and 5. we have $(z_0, t_1) \in \eta^{-1}(\{p_1\}) \cap W_1 \subset K_{d_1}^1(W_1)$ and similarly for (z_0, t_2) . Then (z_0, t_j) has at least d_j coordinates satisfying the inequalities to lie in $K_{d_j}^1$. Hence $z_0 = \text{proj}(z_0, t)$ has at least $d_j - 1$ coordinates satisfying those inequalities for each $j = 1, 2$. For each j , $\text{proj}(W_j)$ is a cube containing z_0 . Subdivide the cubes W_1 and W_2 further so that $\text{proj}(W_1) = \text{proj}(W_2)$. Since $\text{proj}(z_0, t) = z_0$, this means that z_0 has at least $d_j - 1$ coordinates satisfying the inequalities of $K_{d_1}^1(W_1)$ and $K_{d_2}^2(W_2)$. But notice that the inequalities of $K_{d_1}^1(W_1)$ and $K_{d_2}^2(W_2)$ are disjoint (one concerns whether the points are at the front of the cube, the other at the back). So these conditions are disjoint and z_0 must have at least $d_1 + d_2 - 2$ conditions on its coordinates. This is impossible if z_0 has less than $d_1 + d_2 - 3$ coordinates. Hence we are done.

Notice that the proof required $d_1, d_2 \geq 1$. Assume WLOG that $d_2 = 0$, then right from the beginning we are considering the map of homotopy fibers

$$\text{hofiber}_y(X \rightarrow X \cup e^{d_2}) \rightarrow \text{hofiber}_y(X \cup e^{d_1} \rightarrow X \cup e^{d_1} \cup e^{d_2})$$

where $X \cup e^{d_1}$ is now the disjoint union of X with a base point. Then $\text{hofiber}_y(X \rightarrow X \amalg *)$ consists of pairs $(x, \phi) \in X \times \text{Map}(I, X \amalg *)$ such that $\phi(0) \in X$ and $\phi(1) = *$. But $*$ is disjoint from X means that no pairs satisfy this conditions and the homotopy fiber is the empty set. Similarly for the target homotopy fiber. Hence the map of homotopy fibers is the identity and it is trivially true. The proof is similar for $d_1 = 0$. \square

Theorem 1.2.7: Blakers-Massey Theorem for Squares

Let $X_0, X_1, X_2, X_{12} \in \mathbf{CGWH}$ be spaces such that the square

$$\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_{12} \end{array}$$

is a homotopy pushout. Suppose the map $X_0 \rightarrow X_i$ is k_i -connected for $i = 1, 2$. Then the diagram is $(k_1 + k_2 - 1)$ -cartesian. Explicitly, this means that

$$\alpha : X_0 \rightarrow \text{holim}(X_1 \rightarrow X_{12} \leftarrow X_2)$$

is $(k_1 + k_2 - 1)$ -connected.

Proof. By 3.7.29, we only need to consider squares of the form

$$\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_{12} = X_1 \amalg_{X_0} X_2 \end{array}$$

By Hatcher 4.16, if (X, A) is k -connected CW complex, then there exists a CW pair (Z, A) such that $Z \setminus A$ only has cells of dimension $\geq k$ that is weakly equivalent to (X, A) . The set up of the theorem now simplifies to the following: X_1 is the obtained from X_0 by gluing cells of dimension $\geq k_1$, and likewise for X_2 . Now showing that the above diagram is $(k_1 + k_2 - 1)$ -cartesian is the same as showing that the map of homotopy fibers of the vertical maps is $(k_1 + k_2 - 1)$ -connected. This is the same as saying $(\text{holim}(X_1 \rightarrow X_{12}), \text{holim}(X_0 \rightarrow X_1))$ is $(k_1 + k_2)$ -connected, which is the same as saying any map from $(I^n, \partial I^n)$ to the pair of space is homotopic to a map mapping I^n into $\text{holim}(X_0 \rightarrow X_1)$ relative boundary. By a similar method in the above lemma, such a map, by the hom product adjunction, is the same as giving a map $I^n \times I \rightarrow X_{12}$ for which $I^n \times \{1\}$ lies in X_1 . But X_1 is a CW complex and $I^n \times \{1\}$ is compact, which means that image of the map is contained in finitely many cells, and so WLOG we can take X_1, X_2 to be the union of finitely many cells of appropriate dimension.

Now by 1.1.10 and the above lemma we are done. \square

This theorem directly generalizes the homotopy excision theorem in the following way. For X a CW complex and A, B two subcomplexes with non-empty intersection and $X = A \cup B$, consider the following square of inclusions:

$$\begin{array}{ccc} A \cap B & \longrightarrow & A \\ \downarrow & & \downarrow \\ B & \longrightarrow & X \end{array}$$

We have seen that such a square diagram is a homotopy pushout diagram. Now any inclusion map $W \hookrightarrow Z$ is k -connected if and only if (Z, W) is k -connected. So $(A, A \cap B)$ is k_1 -connected and (X, B) is k_2 -connected. Blaker's-Massey theorem implies that

$$\text{hofiber}(A \cap B \rightarrow A) \rightarrow \text{hofiber}(B, X)$$

is $(k_1 + k_2 - 1)$ -connected. But by definition we have an isomorphism $\pi_k(\text{hofiber}(U \rightarrow V)) \cong \pi_{k+1}(V, U)$. So we are really just saying that $\pi_k(A, A \cap B) \rightarrow \pi_k(X, B)$ given by the inclusion is $(k_1 + k_2)$ -connected.

1.3 Excisive Functors Coming From Spectra

While the identity functor is not excisive, there is still a wide class of functors that are excisive, and these functors arise from spectra.

Definition 1.3.1: Spectra

A spectra consists of a collection of spaces X_n and bonding maps $\sigma_n : \Sigma X_n \rightarrow X_{n+1}$ for $n \in \mathbb{N}$ such that σ_n is a weak equivalence.

By the suspension loop adjunction, we will interchangeably refer to the bonding map either as $\Sigma X_n \rightarrow X_{n+1}$ or as $X_n \rightarrow \Omega X_{n+1}$.

Given a space X and a spectrum $\{Y_n, \sigma_n\}$, we can smash X with the spectrum at each level and smashing with the identity will give bonding maps

$$\Sigma(Y_n \wedge X) = S^1 \wedge Y_n \wedge X \xrightarrow{\sigma_n \wedge \text{id}_X} Y_{n+1} \wedge X$$

(we work in **CGWH**) which are usually not weak equivalences. We call them pre-spectra. (2.4.1 foundations of stable homotopy theory)

Theorem 1.3.2

Let $\{K_n, \sigma_n\}$ be a spectrum. Then the functor

$$X \mapsto \operatorname{hocolim}(K_0 \wedge X \rightarrow \Omega(K_1 \wedge X) \rightarrow \Omega^2(K_2 \wedge X) \rightarrow \cdots)$$

is an excisive functor.

2 Spectra as Reduced and Excisive Functors

2.1 Stable Infinity Categories

Definition 2.1.1: Infinity Pushouts

Let \mathcal{C} be an infinity category. Let $F : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}$ be a morphism of simplicial sets. Let $X \in \mathcal{C}$ be an object. We say that X is a pushout in \mathcal{C} if there exists a natural transformation $u : \Delta X \Rightarrow F$ such that there is a homotopy equivalence of Kan complexes:

Definition 2.1.2: Infinity Pullbacks

Why are these the correct analogue?

Definition 2.1.3: Stable Infinity Categories

Let \mathcal{C} be an infinity category. We say that \mathcal{C} is a stable infinity category if the following are true.

- \mathcal{C} has a zero object 0 .
- \mathcal{C} admits all finite limits and colimits.
- A square in \mathcal{C} of the form

$$\begin{array}{ccc} X & \longrightarrow & Y \\ \downarrow & & \downarrow \\ Z & \longrightarrow & W \end{array}$$

is a pushout if and only if it is a pullback.

The definition given here is not the same as that of Lurie's, but Lurie does show that the two definitions are equivalent.

Example in mind: spectra in ordinary categories: pushout=pullback.

2.2 Suspension and Loop Functors

Definition 2.2.1: Suspension Functor

Let \mathcal{C} be an infinity category with a zero object 0 . Define the functor $\Sigma : \mathcal{C} \rightarrow \mathcal{C}$ by sending $X \in \mathcal{C}$ to the pushout of $0 \rightarrow X \leftarrow 0$.

Write M^Σ as the full sub-category of $\text{Func}(\Delta^1 \times \Delta^1, \mathcal{C})$ spanned by pushout squares of the form

$$\begin{array}{ccc} X & \longrightarrow & 0 \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & Y \end{array}$$

The suspension is a functor because we can also define it to be the composition of the section $\mathcal{C} \rightarrow M^\Sigma$ with projection $M^\Sigma \rightarrow \mathcal{C}$ to the bottom right object. The section exists since projection $M^\Sigma \rightarrow \mathcal{C}$ to the first component is a trivial Kan fibration (Kerodon 1.5.5.5). (Lurie HA p.23)

Definition 2.2.2: Loop Functor

Let \mathcal{C} be an infinity category with a zero object 0 . Define the functor $\Omega : \mathcal{C} \rightarrow \mathcal{C}$ by sending $X \in \mathcal{C}$ to the pullback of $0 \leftarrow X \rightarrow 0$.

We can guarantee that looping is a functor in a similar way to Σ .

Proposition 2.2.3

Let \mathcal{C} be a stable infinity category. Then Ω and Σ are both equivalence of infinity categories.

Proof. Let \mathcal{C} be stable. Let $X \in \mathcal{C}$. Then

$$\begin{array}{ccc} X & \longrightarrow & 0 \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \Sigma X \end{array}$$

is a pushout in \mathcal{C} . Since it is also a pullback in \mathcal{C} , we conclude that $\Omega\Sigma X$ and X are equivalent since (co)limits are unique up to equivalence. Similarly, let $Y \in \mathcal{C}$. Then

$$\begin{array}{ccc} \Omega Y & \longrightarrow & 0 \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & Y \end{array}$$

is a pullback and a pushout in \mathcal{C} . We can conclude that $\Sigma\Omega Y$ is weakly equivalent to Y . This shows that Σ is a homotopy inverse of Ω and vice versa. \square

2.3 Excisive Functors between Infinity Categories

Definition 2.3.1: Excisive Functors

Let \mathcal{C}, \mathcal{D} be infinity categories. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor. We say that F is excisive if F sends pushout squares to pullback squares.

Stable infinity categories are infinity categories in which pushouts and pullbacks coincide. In particular, this means that the identity functor is excisive.

Proposition 2.3.2

Let \mathcal{C}, \mathcal{D} be infinity categories. Suppose that \mathcal{C} is pointed and admits all finite colimits. Suppose that \mathcal{D} admits all finite limits. Then

$$\text{Exc}_*(\mathcal{C}, \mathcal{D})$$

is a stable infinity category.

Proof. We first show that $\text{Exc}_*(\mathcal{C}, \mathcal{D})$ is pointed. Let $*$ denote a final object of \mathcal{C} . Since \mathcal{D} admits all finite limits and final objects are limits of the empty diagram, \mathcal{D} admits a final object $*'$. Let $X : \mathcal{C} \rightarrow \mathcal{D}$ be the constant functor given by $X(C) = *'$. It is clear that X is reduced and excisive. Moreover, X is a final object of $\text{Exc}_*(\mathcal{C}, \mathcal{D})$ (Why ???).

Now let $Y \in \text{Exc}_*(\mathcal{C}, \mathcal{D})$. Since X and Y are reduced, the mapping space $\text{Hom}_{\mathcal{D}}(X(*), Y(*))$ is contractible. Consider the restriction map

$$\text{Hom}_{\text{Func}(\mathcal{C}, \mathcal{D})}(X, Y) \rightarrow \text{Hom}_{\mathcal{D}}(X(*), Y(*))$$

given by sending a natural transformation $F : X \Rightarrow Y$ to $F(*) : X(*) \rightarrow Y(*)$. Clearly

$$\begin{array}{ccc} & \mathcal{C} & \\ \text{incl.} \nearrow & & \searrow X \\ * & \xrightarrow{X|_*} & \mathcal{D} \end{array}$$

is a 2-simplex so by prp7.3.6.1 (Kerodon), $\text{Hom}_{\text{Func}(\mathcal{C}, \mathcal{D})}(X, Y) \rightarrow \text{Hom}_{\mathcal{D}}(X(*), Y(*))$ is a homotopy equivalence and so X is an initial object.

prp1.4.2.16 HA

□

We want to give an equivalent characterization of stable infinity categories. Before that we need a technical lemma.

Proposition 2.3.3

Let \mathcal{C}, \mathcal{D} be pointed infinity categories. Suppose that \mathcal{C} admits all finite colimits and \mathcal{D} admits all finite limits. Then the following are equivalent.

- F is reduced and excisive.
- F is reduced and it satisfies the following. For all $X \in \mathcal{C}$, the comparison map

$$\eta_X : F(X) \rightarrow \Omega_{\mathcal{D}}(F(\Sigma_{\mathcal{C}} X))$$

is an equivalence in \mathcal{D} , where η_X is given as follows. For any $X \in \mathcal{C}$, the diagram

$$\begin{array}{ccc} X & \longrightarrow & * \\ \downarrow & & \downarrow \\ * & \longrightarrow & \Sigma_{\mathcal{C}} X \end{array}$$

is a pushout in \mathcal{C} . Sending the diagram through F gives the wanted comparison map η_X by the universal property of limits.

Proof. Let F be reduced and excisive. Notice that following diagram on the left

$$\begin{array}{ccc} X & \longrightarrow & * \\ \downarrow & & \downarrow \\ * & \longrightarrow & \Sigma_{\mathcal{C}} X \end{array} \xRightarrow{F} \begin{array}{ccc} F(X) & \longrightarrow & * \\ \downarrow & & \downarrow \\ * & \longrightarrow & F(\Sigma_{\mathcal{C}} X) \end{array}$$

is a pushout diagram in \mathcal{C} . Applying F gives a pullback diagram on the right. On the other hand, we know that

$$\begin{array}{ccc} \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} X) & \longrightarrow & * \\ \downarrow & & \downarrow \\ * & \longrightarrow & F(\Sigma_{\mathcal{C}} X) \end{array}$$

is a pullback diagram. Since limits in infinity category are unique up to equivalence, the comparison map $F(X) \rightarrow \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} X)$ is an equivalence.

Now suppose that F satisfies the second conditions. Let

$$\begin{array}{ccc} W & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z \end{array}$$

be a pushout square. Consider the following diagram in \mathcal{C} :

$$\begin{array}{ccccccc}
W & \longrightarrow & X & \longrightarrow & 0 & & \\
\downarrow & & \downarrow & & \downarrow & & \\
Y & \longrightarrow & X \amalg_W Y & \longrightarrow & 0 \amalg_W Y & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & X \amalg_W 0 & \longrightarrow & \Sigma_C W & \longrightarrow & \Sigma_C Y \\
& & \downarrow & & \downarrow & & \downarrow \\
& & 0 & \longrightarrow & \Sigma_C X & \longrightarrow & \Sigma_C (X \amalg_W Y)
\end{array}$$

Label the small squares 1 to 7 from left to right and top to bottom. By definition, 1 is a pushout diagram. Since 1 + 2 is a pushout diagram, by the pasting law 2 is a diagram. Similarly, 3 is a pushout diagram. Now 1 + 2 + 3 + 4 is a pushout by definition. Since 1 + 3 is a pushout, 2 + 4 is a pushout diagram. Since 2 is a pushout diagram, 4 is a pushout diagram. Now 2 + 4 + 6 is a pushout diagram by definition. Since 2 + 4 is a pushout, 6 is a pushout. Similarly, 3 + 4 + 5 is a pushout. Since 3 + 4 is a pushout then so is 5. Finally, 4 + 5 + 6 + 7 is a pushout diagram. Since 4 + 6 is a pushout, so is 5 + 7. Since 5 is a pushout, then 7 is a pushout. This proves that all squares 1 to 7 are pushouts. By applying F , we obtain the following diagram:

$$\begin{array}{ccccccc}
F(W) & \longrightarrow & F(X) & \longrightarrow & 0 & & \\
\downarrow & & \downarrow & & \downarrow & & \\
F(Y) & \longrightarrow & F(X \amalg_W Y) & \longrightarrow & F(0 \amalg_W Y) & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & F(X \amalg_W 0) & \longrightarrow & F(\Sigma_C W) & \longrightarrow & F(\Sigma_C Y) \\
& & \downarrow & & \downarrow & & \downarrow \\
& & 0 & \longrightarrow & F(\Sigma_C X) & \longrightarrow & F(\Sigma_C (X \amalg_W Y))
\end{array}$$

Since Z is equivalent to $X \amalg_W Y$, we can remove the top left object and replace it with the pullback so that we obtain a commutative diagram:

$$\begin{array}{ccccccc}
F(W) & \xrightarrow{\quad \mu \quad} & F(X) \times_{F(Z)} F(Y) & \longrightarrow & F(X) & \longrightarrow & 0 \\
& \searrow & \downarrow & & \downarrow & & \downarrow \\
& & F(Y) & \longrightarrow & F(Z) & \longrightarrow & F(0 \amalg_W Y) \longrightarrow 0 \\
& & \downarrow & & \downarrow & & \downarrow \\
& & 0 & \longrightarrow & F(X \amalg_W 0) & \longrightarrow & F(\Sigma_C W) \longrightarrow F(\Sigma_C Y) \\
& & & & \downarrow & & \downarrow \\
& & & & 0 & \longrightarrow & F(\Sigma_C X) \longrightarrow F(\Sigma_C Z)
\end{array}$$

By considering the large square on the left, we obtain a comparison map $F(X) \times_{F(Z)} F(Y) \rightarrow \Omega_{\mathcal{D}} F(\Sigma_C W)$ which will be called θ . Let μ be the comparison map $F(W) \rightarrow F(X) \times_{F(Z)} F(Y)$. Finally, notice that the following diagram on the left sits in the bottom right of the above square, and that we can add 0s to the map so that the limits of the two diagrams remain equivalent (coinitial):

Their limit is precisely computed vertically on each slice and hence is the pullback

$$\Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} X) \times_{\Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} Z)} \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} Y)$$

Since all the diagrams map to each other, we obtain a commutative diagram:

$$\begin{array}{ccc} F(W) & \xrightarrow{\mu} & F(X) \times_{F(Z)} F(Y) \\ & \searrow \simeq & \downarrow \theta \\ & & \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} W) \longrightarrow \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} X) \times_{\Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} Z)} \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} Y) \end{array}$$

where by assumption we have equivalences $F(W) \simeq \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} W)$ hence there are also equivalences on pullbacks. Notice that this implies θ has a left and right homotopy inverse, and hence is an equivalence. By the two out of three property, μ is also an equivalence. Hence F sends pushouts to pullbacks. \square

Proposition 2.3.4

Let \mathcal{C} be an infinity category. Then \mathcal{C} is a stable infinity category if and only if the following are true.

- \mathcal{C} has a zero object 0
- \mathcal{C} admits all finite limits and colimits
- The loop functor $\Omega : \mathcal{C} \rightarrow \mathcal{C}$ is an equivalence of infinity categories.

Proof. It suffices to show that the loop functor is an equivalence if and only if pushout squares and pullback squares coincide. Moreover, we have seen that if \mathcal{C} is stable then Ω is an equivalence.

Conversely, suppose that Ω is an equivalence of infinity categories. Since Σ is adjoint to Ω (HA Lurie p.24), then Σ and Ω are both fully faithful. Choosing the identity functor in prp2.3.4 shows that pushout squares and pullback squares coincide. \square

Proposition 2.3.5

Let \mathcal{C}, \mathcal{D} be stable infinity categories. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor. Then the following are equivalent.

- F commutes with finite limits.
- F is reduced and excisive.

Proof.

- Suppose that F commutes with finite limits. Given a pushout diagram in \mathcal{C} , since \mathcal{C} is stable by prp2.1.3 we know that it is a pullback. Since F commutes with finite limits, F sends the pullback to a pullback. Hence F is excisive. Let $*$ be a final object of \mathcal{C} . Since F is left exact and $*$ is the limit of the empty diagram, $F(*)$ is a final object of \mathcal{D} . Hence F is reduced.
- Suppose that F is reduced and excisive. Start with an equalizer. Then write it as a

fiber. It is a pullback. It is also a pushout since stable. Then F sends this to a pullback. □

2.4 Stable Infinity Categories

Following Lurie, we write $\mathcal{S} = N_{\bullet}^{\text{hc}}(\mathbf{Top}_*)$ for the infinity category of spaces.

Definition 2.4.1: The Infinity Category of Spectra

Define the infinity category of spectra by

$$\text{Sp}(\mathcal{S}) = \lim(\cdots \rightarrow \mathcal{S} \xrightarrow{\Omega} \mathcal{S} \xrightarrow{\Omega} \mathcal{S})$$

Our goal is to show that there is an equivalence between $\text{Sp}(\mathcal{S})$ and $\text{Exc}_*(\mathcal{S}_*^{\text{fin}}, \mathcal{S})$. For that we need to set up some lemmas.

Definition 2.4.2: The Delooping Functor

Let \mathcal{C} be an infinty category that admits all finite limits. Define the delooping functor of \mathcal{C} to be the evaluation functor

$$\Omega_{\mathcal{C}}^{\infty} : \text{Exc}_*(\mathcal{S}_*^{\text{fin}}, \mathcal{C}) \rightarrow \mathcal{C}$$

given on object by $(F : \mathcal{S}_*^{\text{fin}} \rightarrow F(S^0))$

Proposition 2.4.3

Let \mathcal{C} be a pointed infinity category that admits all finite colimits. Let \mathcal{D} be an infinity category that admits all finite limits. Then post composition with Ω^{∞} gives an equivalence of infinity categories

$$\Omega_{\mathcal{D}}^{\infty} \circ - : \text{Exc}_*(\mathcal{C}, \text{Exc}_*(\mathcal{S}_*^{\text{fin}}, \mathcal{D})) \xrightarrow{\cong} \text{Exc}_*(\mathcal{C}, \mathcal{D})$$

Proof. Notice that there is a canonical isomorphism

$$\begin{aligned} \text{Exc}_*(\mathcal{C}, \text{Exc}_*(\mathcal{S}_*^{\text{fin}}, \mathcal{D})) &\simeq \text{Exc}_*(\mathcal{C} \times \mathcal{S}_*^{\text{fin}}, \mathcal{D}) && \text{(Full subcat + adjoint)} \\ &\simeq \text{Exc}_*(\mathcal{S}_*^{\text{fin}}, \text{Exc}_*(\mathcal{C}, \mathcal{D})) \end{aligned}$$

Under this identification, the functor $\Omega^{\infty} \circ -$ corresponds to the functor $\Omega_{\text{Exc}_*(\mathcal{C}, \mathcal{D})}^{\infty}$ since Ω are computed term wise (like all limits). By prp2.2.4 $\text{Exc}_*(\mathcal{C}, \mathcal{D})$ is stable. Hence by prp3.2.2 we conclude that $\Omega_{\text{Exc}_*(\mathcal{C}, \mathcal{D})}^{\infty}$ is an equivalence of infinity categories. Hence $\Omega_{\mathcal{D}}^{\infty} \circ -$ is an equivalence of infinity categories. □

Theorem 2.4.4

There is an equivalence of infinity categories

$$\text{Sp}(\mathcal{S}) \simeq \text{Exc}_*(\mathcal{S}_*^{\text{fin}}, \mathcal{S})$$

Proof.

Since \mathcal{S} is presentable and the infinity category of presentable infinity categories admit all small limits, $\text{Sp}(\mathcal{S})$ is also presentable. Every presentable infinity category admits all small limits and colimits. Since \mathcal{S} is pointed, $\text{Sp}(\mathcal{S})$ is also pointed. Since all limits are computed term-wise, we have that in particular $\Omega_{\text{Sp}(\mathcal{S})}$ is computed term wise. Given $X = \{X_n \mid n \in \mathbb{N}\}$

an object of $\mathrm{Sp}(\mathcal{S})$, $\Omega_{\mathrm{Sp}(\mathcal{S})}X$ is equivalent to X because we have that ΩX_{n+1} is equivalent to X_n for all n . By a prp we conclude that $\mathrm{Sp}(\mathcal{S})$ is stable.

Consider the canonical functor $F : \mathrm{Sp}(\mathcal{S}) \rightarrow \mathcal{S}$ defined by recovering the first factor: $(X_0, X_1, \dots) \mapsto X_0$. It is clear that it commutes with finite limits since limits are computed term-wise. Hence F is left exact. Using the equivalence of infinity categories

$$\Omega^\infty \circ - : \mathrm{Exc}_*^L(\mathrm{Sp}(\mathcal{S}), \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})) \rightarrow \mathrm{Exc}_*^L(\mathrm{Sp}(\mathcal{S}), \mathcal{S})$$

we obtain a factorization

$$\begin{array}{ccc} \mathrm{Sp}(\mathcal{S}) & \xrightarrow{F} & \mathcal{S} \\ & \searrow G \circ - & \nearrow \Omega^\infty \\ & \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S}) & \end{array}$$

Let \mathcal{C} be an arbitrary stable infinity category. By functoriality we obtain a similar factorization:

$$\begin{array}{ccc} \mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Sp}(\mathcal{S})) & \xrightarrow{F \circ -} & \mathrm{Exc}_*^L(\mathcal{C}, \mathcal{S}) \\ & \searrow G \circ - & \nearrow \Omega^\infty \circ - \\ & \mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})) & \end{array}$$

I claim that $F \circ -$ and $\Omega^\infty \circ -$ are equivalences so that $G \circ -$ is an equivalence. The case $\Omega^\infty \circ -$ is already clear. On the other hand, since Ω are computed term-wise (like all limits) and since $\mathrm{Func}(\mathcal{C}, \mathrm{Sp}(\mathcal{S}))$ is right adjoint to products we know that Func commutes with finite limits. Thus we have that

$$\mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Sp}(\mathcal{S})) = \lim(\dots \rightarrow \mathrm{Exc}_*^L(\mathcal{C}, \mathcal{S}) \xrightarrow{\Omega^\infty \circ -} \mathrm{Exc}_*^L(\mathcal{C}, \mathcal{S}) \xrightarrow{\Omega^\infty \circ -} \mathrm{Exc}_*^L(\mathcal{C}, \mathcal{S}))$$

Now $\Omega_{\mathcal{S}} \circ -$ is an equivalence because $\mathrm{Exc}_*(\mathcal{C}, \mathcal{S})$ is stable (because \mathcal{C} is stable and \mathcal{S} admits all finite (co)limits). We conclude that $\mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Sp}(\mathcal{S})) \simeq \mathrm{Exc}_*^L(\mathcal{C}, \mathcal{S})$. Thus evaluation on the first factor $F \circ - : \mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Sp}(\mathcal{S})) \rightarrow \mathrm{Exc}_*^L(\mathcal{C}, \mathcal{S})$ is an equivalence of infinity categories.

From the fact that $G \circ -$ is an equivalence, we have an equivalence

$$\mathrm{Exc}_*(\mathcal{C}, \mathrm{Sp}(\mathcal{S})) = \mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Sp}(\mathcal{S})) \simeq \mathrm{Exc}_*^L(\mathcal{C}, \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})) = \mathrm{Exc}_*(\mathcal{C}, \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S}))$$

for all stable infinity categories \mathcal{C} . By the Yoneda lemma we conclude that $\mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$ and $\mathrm{Sp}(\mathcal{S})$ are equivalent. \square

Here notice that we are taking excisive functors from $\mathcal{S}_*^{\mathrm{fin}}$ to \mathcal{S} instead of functors from \mathcal{S} . This has the same effect as taking finitary functors in the ordinary-categorical case. In both cases we would like the functor to be determined on finite colimits.

More: F in the proof is precisely Ω^∞ once we prove equivalence $\mathrm{Sp}(\mathcal{S}) \simeq \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$. It has an adjoint Σ^∞ sending X to its suspension spectrum. Through the composition we see that $F \in \mathrm{Exc}_*(\mathcal{S}_*^{\mathrm{fin}}, \mathcal{S})$ corresponds to the spectrum $\Sigma^\infty F(S^0) \simeq \{F(S^n)\}$.

3 From Functors to Excisive Functors

3.1 Goodwillie Calculus

Definition 3.1.1: T_1 of a Functor

Let F be a homotopy functor. Let X be a space. Define

$$T_1 F(X) = \operatorname{holim}(F(CX) \rightarrow F(\Sigma X) \leftarrow F(CX))$$

It is clear that given a map $X \rightarrow Y$, this induces maps $CX \rightarrow CY$ and $\Sigma X \rightarrow \Sigma Y$. And the definition of the homotopy pullback tells us that $T_1 F$ is a functor. Any natural transformation $F \Rightarrow G$ gives maps $F(CX) \rightarrow G(CX)$ and $F(\Sigma X) \rightarrow G(\Sigma X)$ so that T_1 itself is a functor that sends functors to functors. Finally, there is a natural transformation $t_1(F) : F \Rightarrow T_1 F$ since for each X there is a natural map $F(X) \rightarrow \operatorname{holim}(F(CX) \rightarrow F(\Sigma X) \leftarrow F(CX))$.

Definition 3.1.2: P_1 of a Functor

Let F be a homotopy functor. Let X be a space. Define

$$P_1 F(X) = \operatorname{hocolim}(F(X) \xrightarrow{t_1(F)(X)} T_1 F(X) \xrightarrow{t_1(T_1 F)(X)} T_1(T_1 F)(X) \rightarrow \cdots)$$

Since t_1 is natural transformation, we again obtain appropriate commutative diagrams so that $P_1 F$ becomes a functor.

Example 3.1.3

If F is reduced, then there is an easy way to describe the two functors. Namely, CX is contractible so $T_1 F(X) = \Omega F(\Sigma X)$. Then

$$T_1(T_1(F))(X) = \Omega(T_1 F)(\Sigma X) = \Omega(\Omega F(\Sigma(\Sigma X))) = \Omega^2 F(\Sigma^2 X)$$

Generalizing, we obtain

$$P_1 F(X) = \operatorname{hocolim}_{n \in \mathbb{N}} \Omega^n F(\Sigma^n X)$$

We borrow terminology from Goodwillie

Definition 3.1.4

Let $F : \mathbf{Spaces} \rightarrow \mathbf{Spaces}$ be a homotopy functor. We say that F is $E(c, k)$ if the following are true. For all homotopy pushout squares

$$\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_{12} \end{array}$$

such that the top horizontal map is k_1 -connected and the left vertical map is k_2 -connected for $k_1, k_2 \geq k$, then F of the square is $(k_1 + k_2 - c)$ -cartesian.

Since any map is (-1) -connected, every homotopy functor is $E(-1, -1)$.

id is $E(1, -1)$

If F is $E(-\infty, -1)$ then F is excisive.

If F is $E(c, k)$, then F is $E(c, k - 1)$. This follows from the fact that every n -connected map is $(n - 1)$ -connected.

Proposition 3.1.5

Let $F : \mathbf{Spaces} \rightarrow \mathbf{Spaces}$ be a homotopy functor. Suppose that F is $E(c, k)$, then $T_1 F$ is $E(c-1, \max\{k-1, -1\})$.

The maximum in the formula is to prevent $(-n)$ -connected maps to appear in the discussion for large n .

Theorem 3.1.6

Let $F : \mathbf{Spaces} \rightarrow \mathbf{Spaces}$ be a homotopy functor. Then $P_1 F$ is excisive.

Proof. All maps are trivially (-1) -connected. Hence F is $E(-1, -1)$. Induct on n to see that $T_1^n F$ is $E(-n, -1)$. Since $P_1 F$ is the homotopy colimit of $T_1^n F$ as $n \rightarrow \infty$, we conclude that $P_1 F$ is $E(-\infty, -1)$. \square

Example 3.1.7

Id \rightarrow Infinite loop suspension

3.2 Spectra and (Co)Homology Theories**Definition 3.2.1: Reduced Homology Theory**

A reduced homology theory is a collection of functors and natural transformations

$$H_n : \mathbf{CGWH} \rightarrow \mathbf{Ab} \quad \text{and} \quad s_n : H_n \Rightarrow H_{n+1} \circ \Sigma$$

such that the following axioms are satisfied.

- If $f \simeq g : X \rightarrow Y$ are homotopic, then $H_n(f) = H_n(g)$
- If $f : X \rightarrow Y$ is a map then there is an exact sequence

$$H_n(X) \xrightarrow{f_*} H_n(Y) \xrightarrow{j_*} H_n(C_f)$$

where $j : X \rightarrow C_f$ is the inclusion.

- The natural transformation gives an isomorphism

$$s_n(X) : H_n(X) \rightarrow H_{n+1}(\Sigma X)$$

for all n .

- For any wedge product $X = \bigvee_k X_k$, the inclusion maps induces an isomorphism

$$\bigoplus_k H_n(X_k) \cong H_n(X)$$

- If $f : X \rightarrow Y$ is a weak homotopy equivalence, then $H_n(f)$ is an isomorphism.

(Davies / Switzer)

Definition 3.2.2: Homology Theory Associated to Spectra

Let $\{K_n \mid n \in \mathbb{N}\}$ be a spectrum. Define a functor $E_n : \mathbf{Spaces} \rightarrow \mathbf{Ab}$ by

$$E_n(X) = \lim_{k \rightarrow \infty} \pi_{n+k}(X \wedge K_k)$$

and natural transformations $s_n : E_n \Rightarrow E_{n+1} \circ \Sigma$ given by the structure maps of the spectrum.

Here, the maps defining the direct limit $\pi_{n+k}(X \wedge K_k) \rightarrow \pi_{n+1+k}(X \wedge K_{k+1})$ are given by

$$\pi_{n+k}(X \wedge K_k) \xrightarrow{\Sigma} \pi_{n+1+k}(S^1 \wedge X \wedge K_k) \xrightarrow{\text{id}_X \wedge \sigma_n} \pi_{n+1+k}(X \wedge K_{k+1})$$

(we are working in **CGWH**) Moreover, it is a functor since any map $f : X \rightarrow Y$ wedges with the identity to give a map $X \wedge K_k \rightarrow Y \wedge K_k$. The homotopy group functor gives a map of homotopy groups. And the universal property of direct limits give the induced map. (Davies p.229)

4 Appendix

4.1 Homotopical Connectivity

2.6 cubical homotopy theory

Definition 4.1.1: n -Connected Spaces

Let X be a space. Let $n \in \mathbb{N}$. We say that X is n -connected if for all $-1 \leq k \leq n$, any map $S^k \rightarrow X$ is homotopic to the constant map to the base point.

Every non-empty space is (-1) -connected.

Definition 4.1.2: n -Connected Spaces

Let (X, A) be a pointed pair of spaces. Let $n \in \mathbb{N}$. We say that (X, A) is n -connected if for all $-1 \leq k \leq n$, any map $(D^k, \partial D^k) \rightarrow (X, A)$ is homotopic to a map $(D^k, \partial D^k) \rightarrow (A, A)$ relative to boundary.

Definition 4.1.3: n -Connected Maps

Let X, Y be spaces. Let $f : X \rightarrow Y$ be a map. We say that f is n -connected if (M_f, X) is n -connected.

Proposition 4.1.4

Let X be a space. Let $n \in \mathbb{N}$. Then the following are equivalent.

- X is n -connected.
- $\pi_k(X) = 0$ for all $0 \leq k \leq n$.
- For all $-1 \leq k \leq n$, every map $S^k \rightarrow X$ extends to a map $D^{k+1} \rightarrow X$.
- (CX, X) is $(n+1)$ -connected.

Proposition 4.1.5

Let (X, A) be a space. Let $n \in \mathbb{N}$. Then the following are equivalent.

- (X, A) is n -connected
- For all $0 < k \leq n$, $\pi_k(X, A) = 0$ and $\pi_0(A) \rightarrow \pi_0(X)$ is surjective.
- $\iota : A \hookrightarrow X$ is n -connected.

Proposition 4.1.6

Let X, Y be spaces. Let $f : X \rightarrow Y$ be a map. Let $n \in \mathbb{N}$. If X is not empty, then the following are equivalent.

- f is n -connected
- $\text{hofiber}_y(f)$ is n -connected for all $y \in Y$.
- For all $0 < k \leq n$, $\pi_k(f)$ is an isomorphism and $\pi_n(f)$ is surjective.

Every map is (-1) -connected since every non-empty space is (-1) -connected.

4.2 Weak Equivalences

Definition 4.2.1: Weak Equivalences

Let X, Y be spaces. Let $f : X \rightarrow Y$ be a map. We say that f is a weak equivalence if

$$\pi_n(f) : \pi_n(X) \rightarrow \pi_n(Y)$$

is an isomorphism for all n .

Clearly f is a weak equivalence if and only if f is n -connected for all n .

Example 4.2.2: No Going Backwards

S^1 with pseudocircle.

Proposition 4.2.3: Two-Out-Of-Three Property

Let X, Y, Z be spaces. Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be maps. If any two of $f, g, g \circ f$ are weak equivalences, then so is the third one.

Proof. If f and g are weak equivalences then it is clear that $g \circ f$ is a weak equivalence. If $g \circ f$ and f are weak equivalences but g is not, then $\pi_n(g)$ is not an isomorphism implies that $\pi_n(g \circ f)$ is not an isomorphism, a contradiction. Similarly if $g \circ f$ and g are weak equivalences and f is not, then $\pi_n(g \circ f)$ is not an isomorphism, a contradiction. \square

4.3 Some Important Facts**Proposition 4.3.1**

The infinity categories \mathcal{S} and \mathbf{Cat}_∞ is complete and cocomplete.

Fabian I.35

Limits of functors can be computed pointwise:

Proposition 4.3.2

Let $\mathcal{C}, \mathcal{D}, \mathcal{E}$ be infinity categories. Let $F : \mathcal{D} \rightarrow \mathcal{E}$ be a functor. Then the induced functor

$$- \circ F : \mathbf{Func}(\mathcal{E}, \mathcal{C}) \rightarrow \mathbf{Func}(\mathcal{D}, \mathcal{C})$$

preserves limits and colimits.

In particular, by choosing the inclusion functor $\{d\} \hookrightarrow \mathcal{D}$, we obtain the (co)limit preserving functor

$$\mathrm{ev}_d : \mathbf{Func}(\mathcal{D}, \mathcal{C}) \rightarrow \mathbf{Func}(\{d\}, \mathcal{C}) \simeq \mathcal{C}$$

Now given any diagram $X : K \rightarrow \mathbf{Func}(\mathcal{D}, \mathcal{C})$ that admits a limit, $\lim_K X$ is an object in $\mathbf{Func}(\mathcal{D}, \mathcal{C})$. To compute the value of this functor at $d \in \mathcal{D}$, we use the evaluation map to get

$$\left(\lim_K X \right) (d) = \mathrm{ev}_d \left(\lim_K X \right) = \lim_K (\mathrm{ev}_d \circ X)$$

where the limit on the right is now an object in \mathcal{C} , and the diagram of the limit is given on objects by $F(d)$ for all F in the image of X . (I.39 Fabian)
